

# Particle Accelerators

Eric Prebys, FNAL

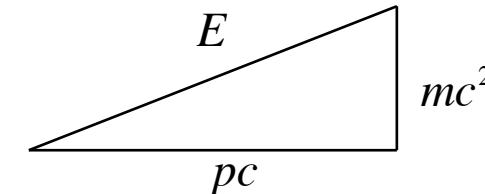

# Comments

- This talk will focus primarily on the evolution of the highest energy particle accelerators
  - This has largely driven the development of the technology; however
  - High energy research machines are a tiny fraction (~1%) of the particle accelerators in use today.
- I'll be fairly technical
  - In the end, you should have a fairly quantitative understanding of most of the accelerator jargon you'll hear in a typical high energy physics talk:
    - “Lattice”
    - “Beta function”
    - “Tune”
    - “Emittance”
    - “RF”
    - etc...

# Relativity and Units

Remember forever!

- Basic Relativity

$$\beta \equiv \frac{v}{c}$$

$$\gamma \equiv \frac{1}{\sqrt{1 - \beta^2}}$$

momentum  $p = \gamma mv$

total energy  $E = \gamma mc^2$

kinetic energy  $K = E - mc^2$

$$E^2 = \sqrt{(mc^2)^2 + (pc)^2}$$

Some Handy Relationships

$$\beta = \frac{pc}{E}$$

$$\gamma = \frac{E}{mc^2}$$

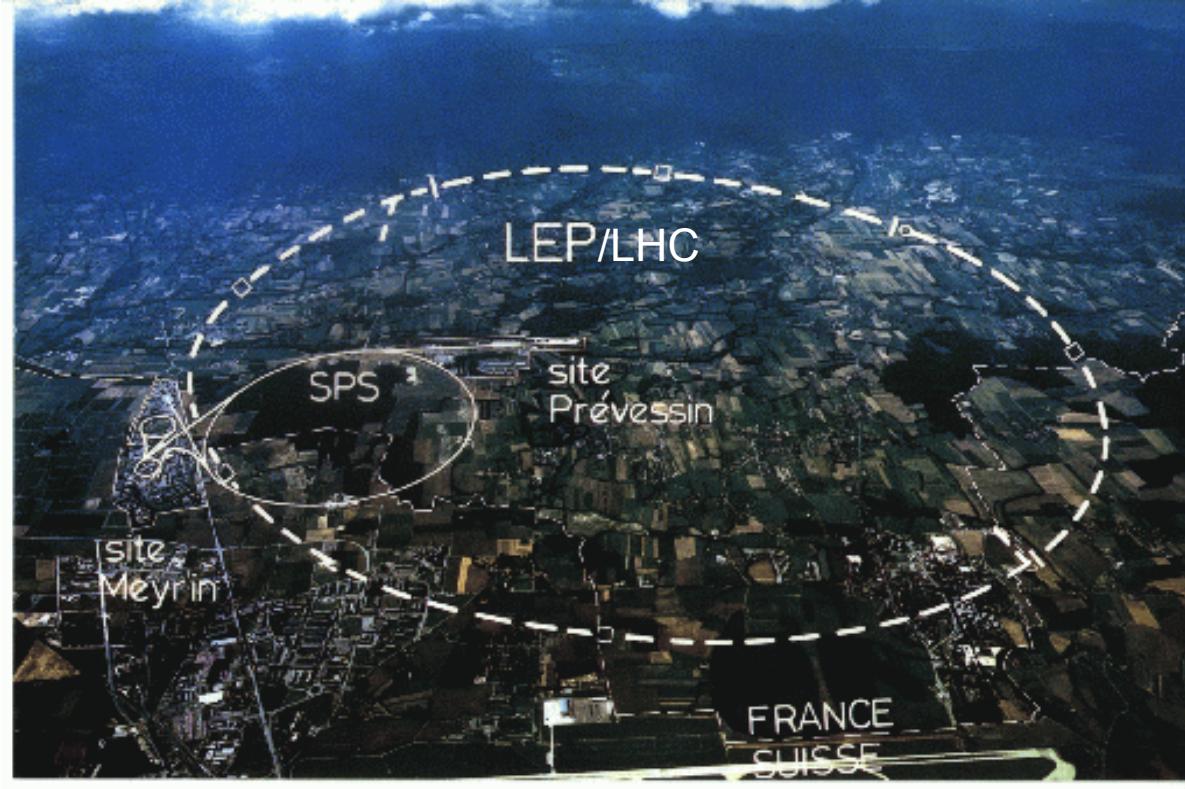

$$\beta\gamma = \frac{pc}{mc^2}$$

- Units

- For the most part, we will use SI units, except
  - Energy: eV (keV, MeV, etc) [1 eV =  $1.6 \times 10^{-19}$  J]
  - Mass:  $eV/c^2$  [proton =  $1.67 \times 10^{-27}$  kg = 938 MeV/c<sup>2</sup>]
  - Momentum:  $eV/c$  [proton @  $\beta=.9$  = 1.94 GeV/c]
- In the US and Europe, we normally talk about the kinetic energy ( $K$ ) of a particle beam, although we'll see that momentum really makes more sense.

These units make these relationships really easy to calculate

# State of the Art: Large Hadron Collider (LHC)

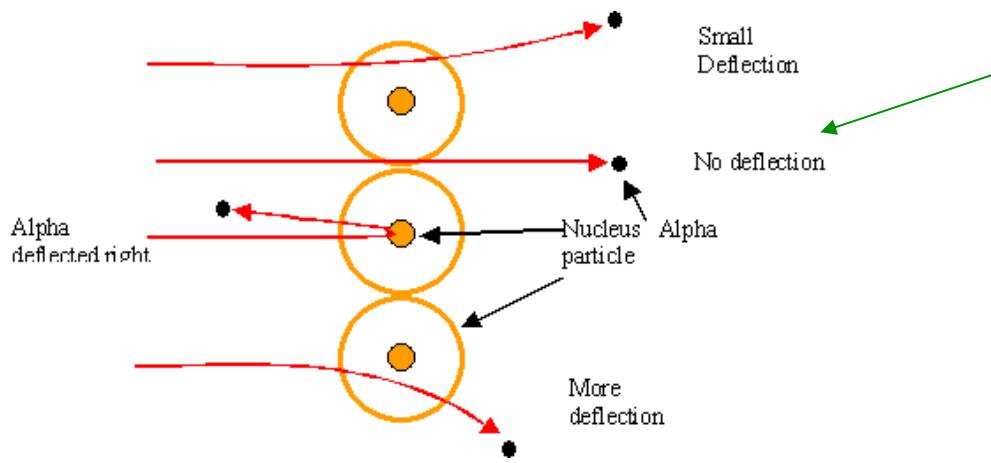

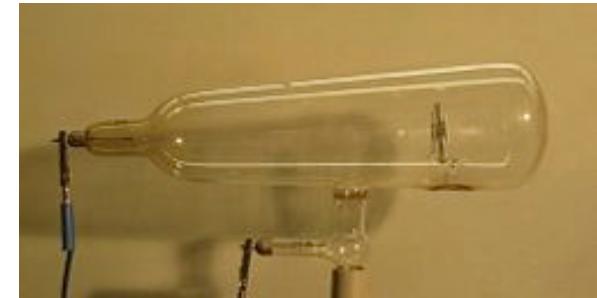

- Built at CERN, straddling the French/Swiss border
- 27 km in circumference
- Currently colliding beams of 6.5 TeV/beam
  - Design energy of 7 TeV
- That's where we are. Now let's see how we got here...

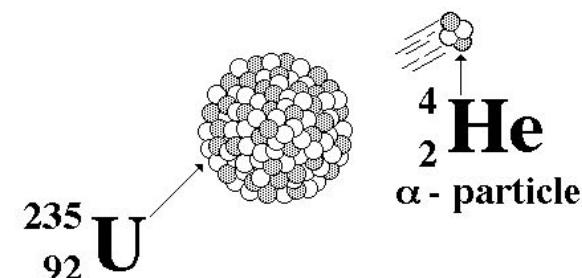

# Rewind: Some Pre-History

- The first artificial acceleration of particles was done using “Crookes tubes”, in the latter half of the 19<sup>th</sup> century
  - These were used to produce the first X-rays (1875)
  - At the time no one understood what was going on
- The first “particle physics experiment” told Ernest Rutherford the structure of the atom (1911)

Study the way radioactive particles “scatter” off of atoms

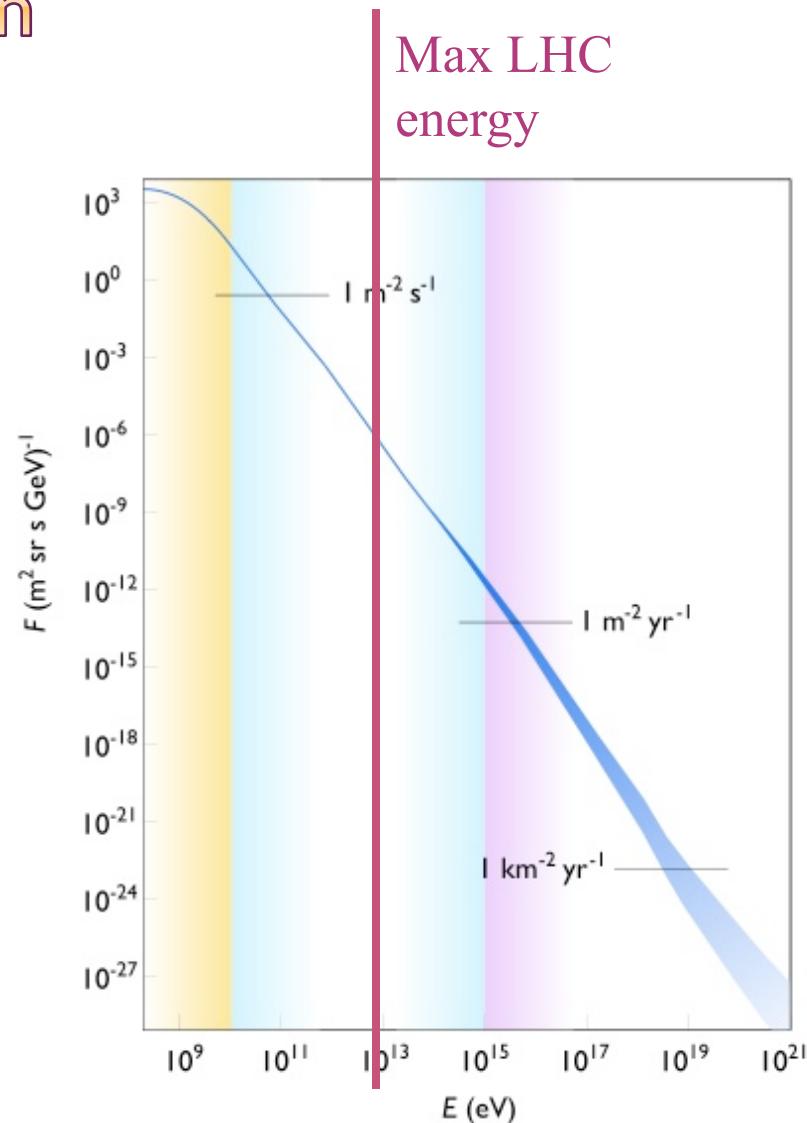

- In this case, the “accelerator” was a naturally decaying  $^{235}\text{U}$  nucleus

# Natural Particle Acceleration

- Radioactive sources produce maximum energies of a few million electron volts (MeV)
- Cosmic rays reach energies of  $\sim 1,000,000,000 \times$  LHC but the rates are too low to be useful as a study tool
  - Not enough “luminosity”
- However, low energy cosmic rays are extremely useful for detector testing, commissioning, etc.

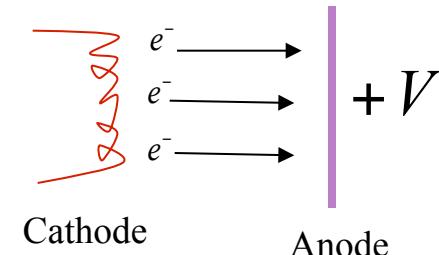

# Man-made Particle Acceleration

The simplest accelerators accelerate charged particles through a *static* electric field. Example: **vacuum tubes** (or CRT TV's)

$$K = eEd = eV$$

Limited by magnitude of electric field:

- CRT display ~keV
- X-ray tube ~10's of keV
- Van de Graaf ~MeVs

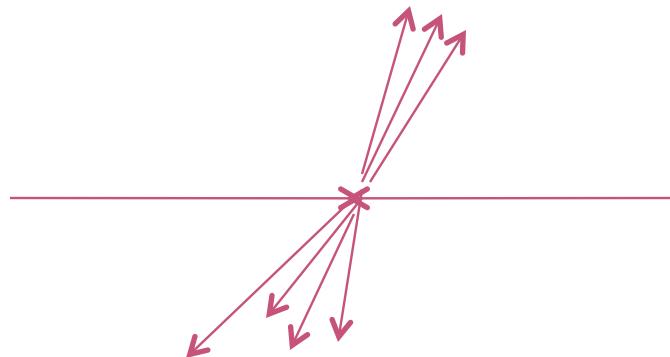

Solutions:

- Alternate fields to keep particles in accelerating fields -> **Radio Frequency (RF) acceleration**
- Bend particles so they see the same accelerating field over and over -> **cyclotrons, synchrotrons**

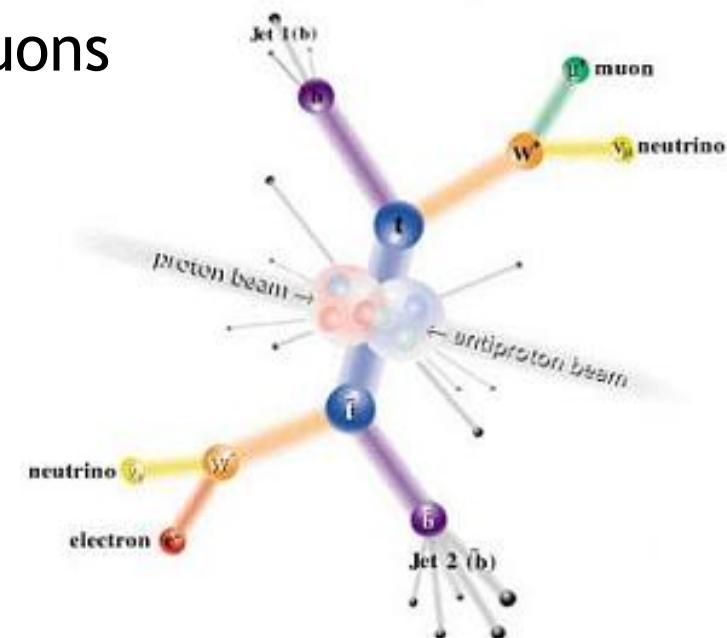

Old FNAL Cockcroft-Walton = 750 kV

# Interlude: Electrons vs. Protons

- Electrons are point-like
  - Well-defined initial state
  - Full energy available to interaction

- Protons are made of quarks and gluons
  - Interaction take place between these constituents.
  - Only a small fraction of energy available, not well-defined.
  - Rest of particle fragments -> big mess!

So why not stick to electrons?

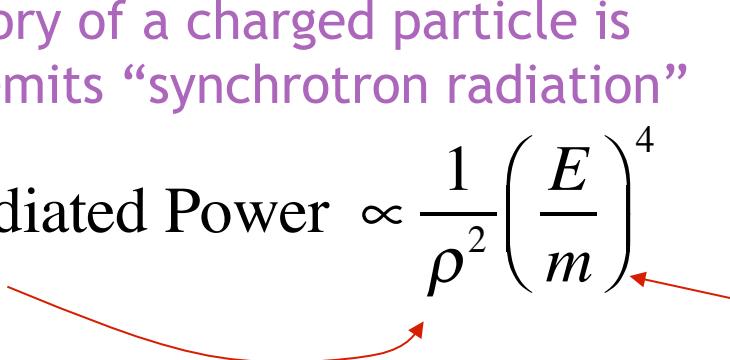

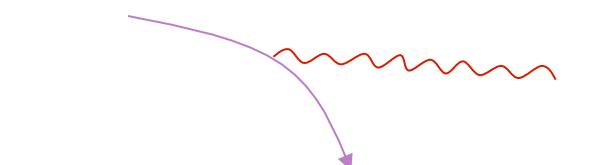

# Synchrotron Radiation

As the trajectory of a charged particle is deflected, it emits “synchrotron radiation”

$$\text{Radiated Power} \propto \frac{1}{\rho^2} \left( \frac{E}{m} \right)^4$$

Radius of curvature

An electron will radiate about  $10^{13}$  times more power than a proton of the same energy!!!!

- **Protons:** Synchrotron radiation does not affect kinematics very much
  - Energy limited by strength of magnetic fields and size of ring
- **Electrons:** Synchrotron radiation dominates kinematics
  - To go higher energy, we have to *lower* the magnetic field and go to *huge* rings
  - Eventually, we lose the benefit of a circular accelerator, because we lose all the energy each time around.

Since the beginning, the “energy frontier” has belonged to proton (and/or antiproton) machines, while electrons are used for precision studies and other purposes.

Now, back to the program...

# The Cyclotron (1930's)

- A charged particle in a uniform magnetic field will follow a circular path of radius

$$\rho = \frac{p}{qB} \approx \frac{mv}{qB} \quad (v \ll c)$$

$$f = \frac{v}{2\pi\rho}$$

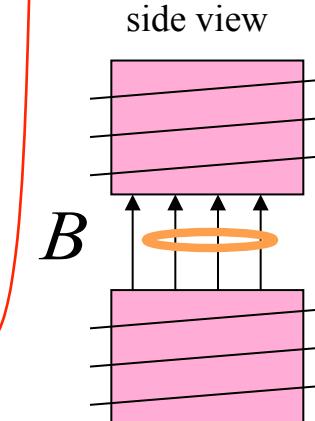

$$= \frac{qB}{2\pi m} \quad (\text{constant!!})$$

$$\Omega_s = \frac{f}{2\pi} = \frac{qB}{m}$$

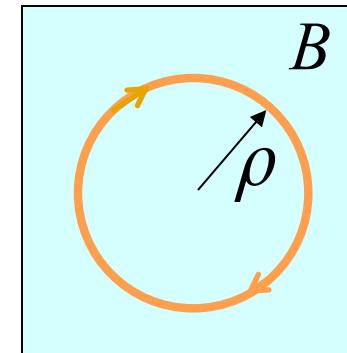

For a proton:

$f_c = 15.2 \times B[T] \text{ MHz}$   
i.e. "RF" range

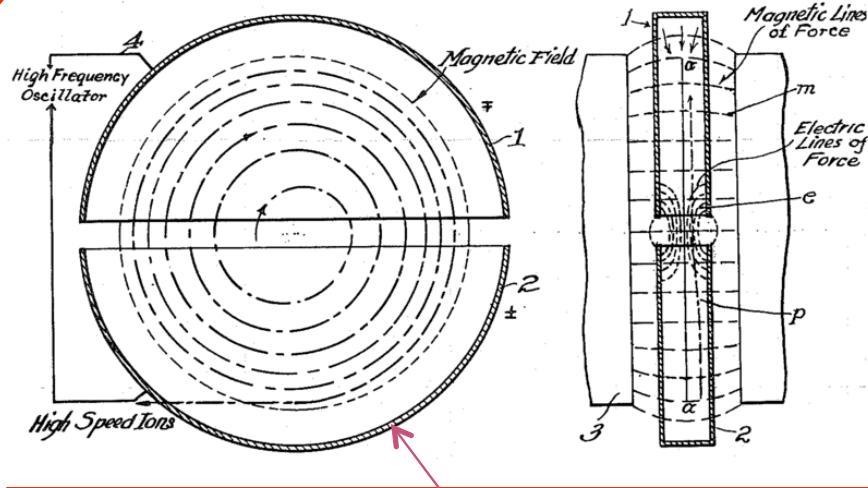

would not work for electrons!

top view

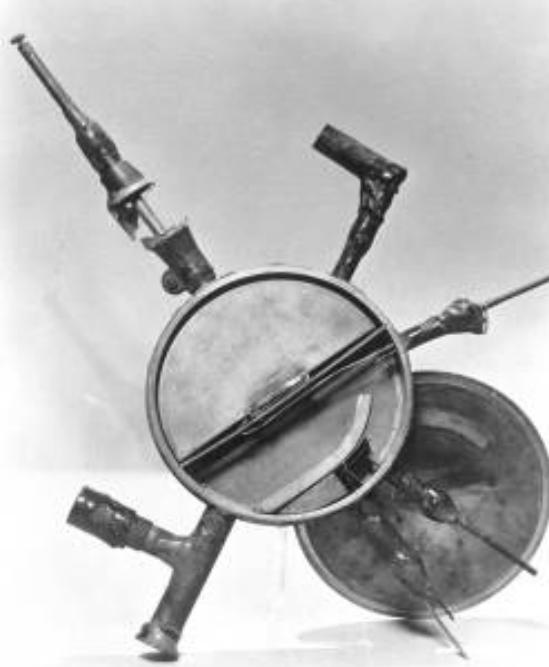

"Cyclotron Frequency"

Accelerating "DEES": by applying a voltage which oscillates at  $f_c$ , we can accelerate the particle a little bit each time around, allowing us to get to high energies with a relatively small voltage.

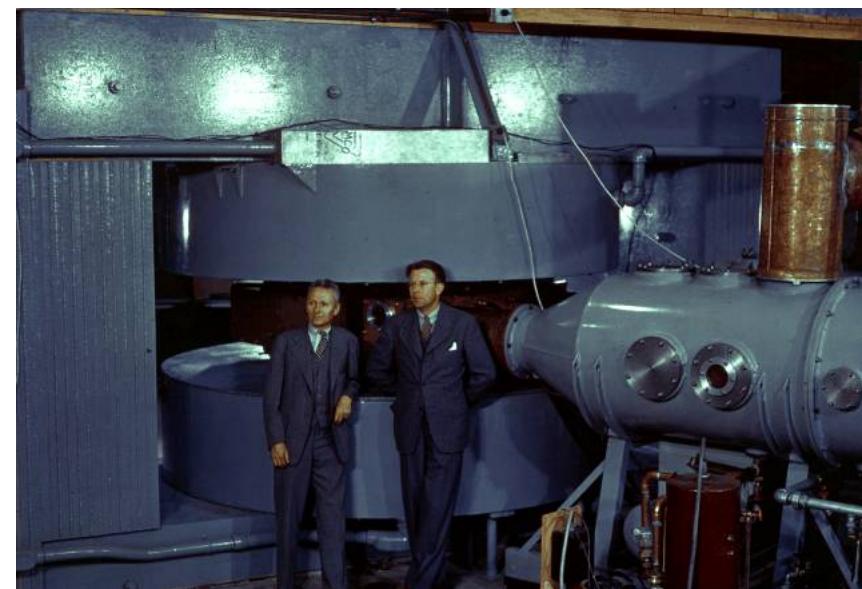

# Round and Round We Go: the First Cyclotrons

- 1935 - 60" Cyclotron
  - Lawrence, et al. (LBL)
  - ~19 MeV ( $D_2$ )
  - Prototype for many

- ~1930 (Berkeley)

- Lawrence and Livingston
- $K=80 \text{ keV}$
- Fit in your hand

# Onward and Upward!

- Cyclotrons were limited by three problems
  - Constant frequency breaks down at ~10% speed of light
    - Solved with variable frequency “synchro-cyclotrons”
      - phase stability (more about this later)
  - As energy goes up, magnet gets huge
  - Beams are not well focused and get larger with energy
- Two major advances allowed accelerators to go beyond the energies and intensities possible at cyclotrons
  - “Synchrotron” - in which the magnetic field is increased as the energy increases (proportional to momentum), such that particles continue to follow the same path .
  - “Strong focusing” - a technique in which magnetic gradients (non-uniform fields) are used to focus particles and keep them in a smaller beam pipe than was possible with cyclotrons.
- Note: still plenty of uses for cyclotrons (simple, inexpensive, rapid cycling)
  - Medical treatments
  - Isotope production
  - Nuclear physics

# Understanding Beam Motion: Beam “rigidity”

- The relativistically correct form of Newton's Laws for a particle in an electromagnetic field is:

$$\vec{F} = \frac{d\vec{p}}{dt} = q(\vec{E} + \vec{v} \times \vec{B}); \quad \vec{p} = \gamma m \vec{v}$$

- A particle of unit charge in a uniform magnetic field will move in a circle of radius

$$\rho = \frac{p}{eB}$$

$$\rightarrow (B\rho) = \frac{p}{e}$$

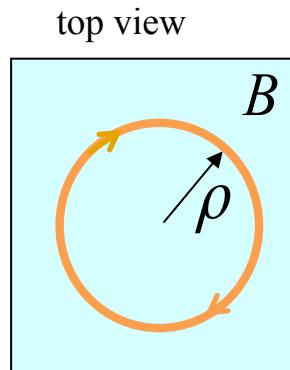

constant for fixed energy!

$$T \cdot m^2/s = V \rightarrow (B\rho)_c = \frac{pc}{e}$$

units of eV in our usual convention

Beam “rigidity” = constant at a given momentum (even when  $B=0!$ )

$$(B\rho)[T \cdot m] = \frac{p[eV/c]}{c[m/s]} \approx \frac{p[MeV/c]}{300}$$

Remember forever!

If all magnetic fields are scaled with the momentum as particles accelerate, the trajectories remain the same  
 → “synchrotron” [E. McMillan, 1945]

# Example Beam Parameters

- Compare Fermilab LINAC ( $K=400$  MeV) to LHC ( $K=7000$  GeV)

Parameter	Symbol	Equation	Injection	Extraction
proton mass	$m$ [GeV/c <sup>2</sup> ]		0.938	
kinetic energy	$K$ [GeV]		.4	7000
total energy	$E$ [GeV]	$K + mc^2$	1.3382	7000.938
momentum	$p$ [GeV/c]	$\sqrt{E^2 - (mc^2)^2}$	0.95426	7000.938
rel. beta	$\beta$	$(pc)/E$	0.713	0.999999991
rel. gamma	$\gamma$	$E/(mc^2)$	1.426	7461.5
beta-gamma	$\beta\gamma$	$(pc)/(mc^2)$	1.017	7461.5
rigidity	$(B\rho)$ [T-m]	$p[\text{GeV}]/(.2997)$	3.18	23353.

This would be the radius of curvature in a 1 T magnetic field or the field in Tesla needed to give a 1 m radius of curvature.

# Weak Focusing

- Cyclotrons relied on the fact that magnetic fields between two pole faces are never perfectly uniform.
- This prevents the particles from spiraling out of the pole gap.
- In early synchrotrons, radial field profiles were optimized to take advantage of this effect, but in any weak focused beams, *the beam size grows with energy*.
- The highest energy weak focusing accelerator was the Berkeley Bevatron, which had a kinetic energy of 6.2 GeV
  - High enough to make antiprotons (and win a Nobel Prize)
  - It had an aperture 12"x48"!

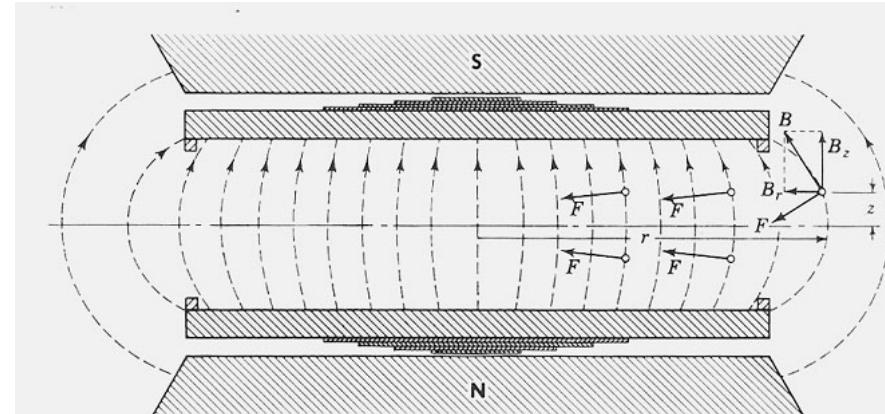

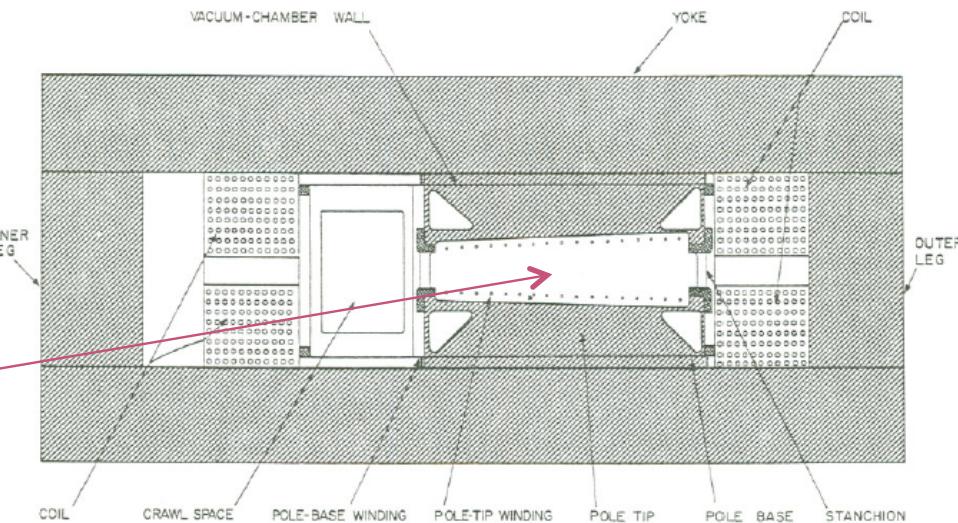

Fig. 6-7. Radially decreasing magnetic field between poles of a cyclotron magnet, showing shims for field correction.

# Strong Focusing

- Strong focusing utilizes alternating magnetic gradients to precisely control the focusing of a beam of particles
  - The principle was first developed in 1949 by Nicholas Christofilos, a Greek-American engineer, who was working for an elevator company in Athens at the time.
  - Rather than publish the idea, he applied for a patent, and it went largely ignored.
  - The idea was independently invented in 1952 by Courant, Livingston and Snyder, who later acknowledged the priority of Christofilos' work.
  - Courant and Snyder wrote a follow-up paper in 1958, which contains the vast majority of the accelerator physics concepts and formalism in use to this day!
- Although the technique was originally formulated in terms of magnetic gradients, it's much easier to understand in terms of the separate functions of dipole and quadrupole magnets.

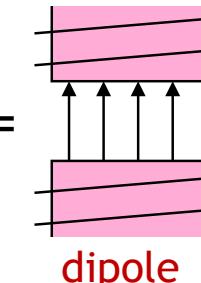

# Combined Function vs. Separated Function

Strong focusing was originally implemented by building magnets with non-parallel pole faces to introduce a linear magnetic gradient

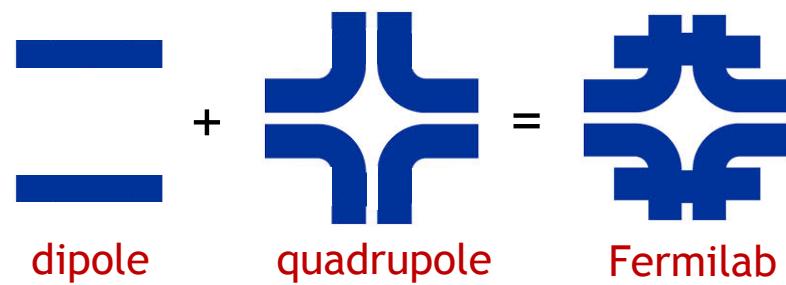

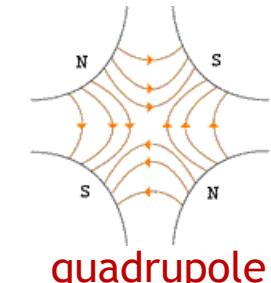

CERN PS (1959, 29 GeV)

$$B_y(x) = B_0 + \frac{\partial B_y}{\partial x} x$$

+

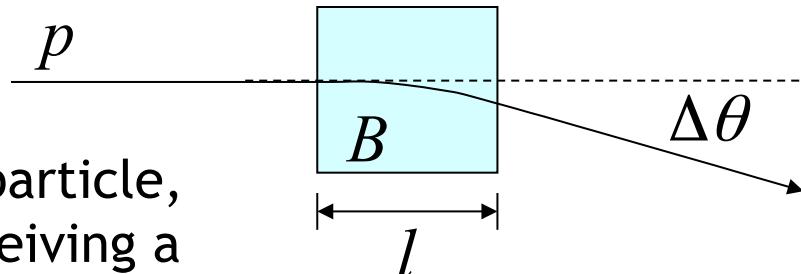

Strong focusing is also much easier to *teach* using separated functions, so we will...

# Thin Lens Approximation and Magnetic “kick”

- If the path length through a transverse magnetic field is short compared to the bend radius of the particle, then we can think of the particle receiving a transverse “kick”, which is proportional to the integrated field

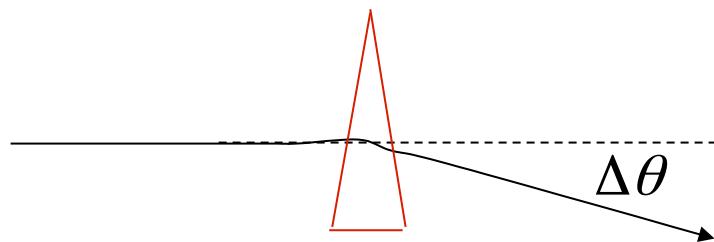

$$p_{\perp} \approx qvBt = qvB(l/v) = qBl$$

and it will be bent through small angle

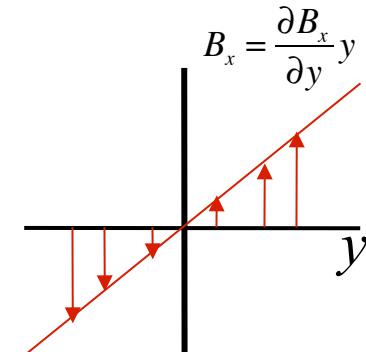

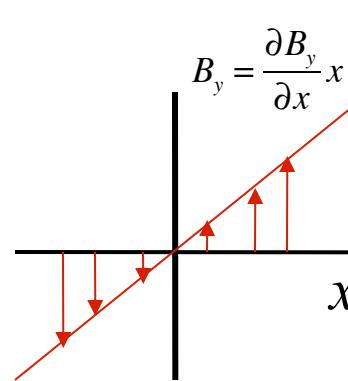

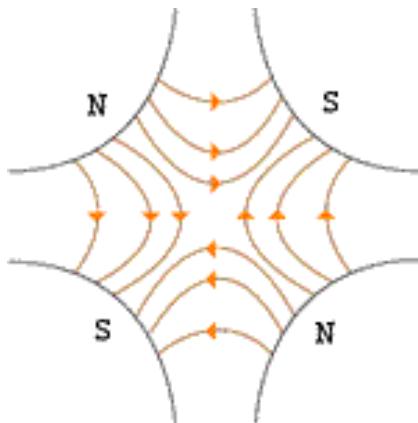

$$\Delta\theta \approx \frac{p_{\perp}}{p} = \frac{Bl}{(B\rho)}$$

- In this “thin lens approximation”, a dipole is the equivalent of a prism in classical optics.

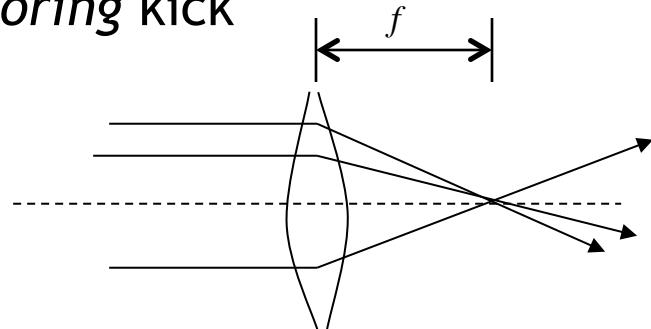

# Quadrupole Magnets\* as Lenses

$$\text{Note: } \vec{\nabla} \times \vec{B} = 0 \rightarrow \frac{\partial B_y}{\partial x} = \frac{\partial B_x}{\partial y} \equiv B'$$

- A positive particle coming out of the page off center in the horizontal plane will experience a *restoring kick proportional to the displacement*

$$\Delta\theta \approx -\frac{B_y l}{(B\rho)} = -\frac{B' l x}{(B\rho)}$$

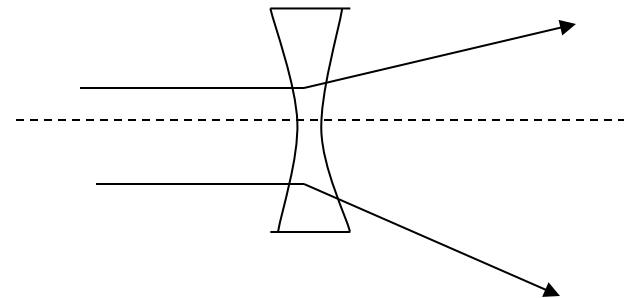

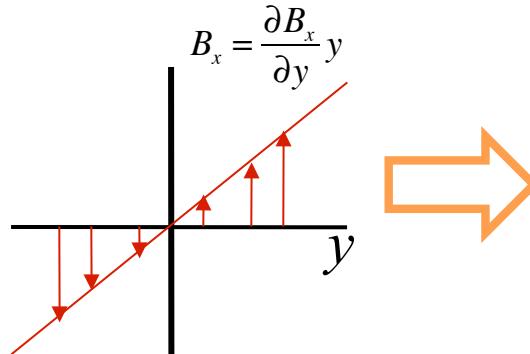

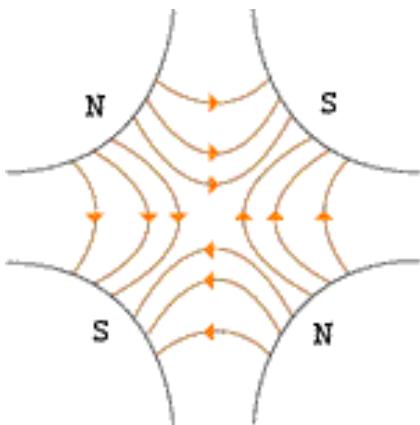

just like a “thin lens”  
with focal length

\*or quadrupole term in a gradient magnet

$$f = \frac{x}{\Delta\theta} = \frac{(B\rho)}{B' l}$$

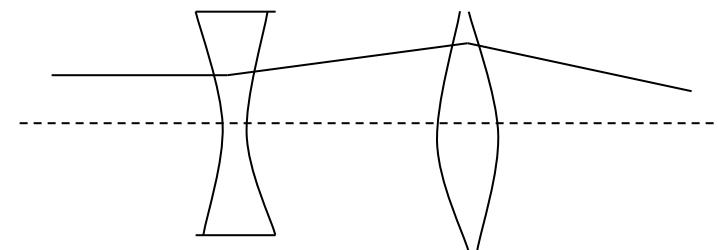

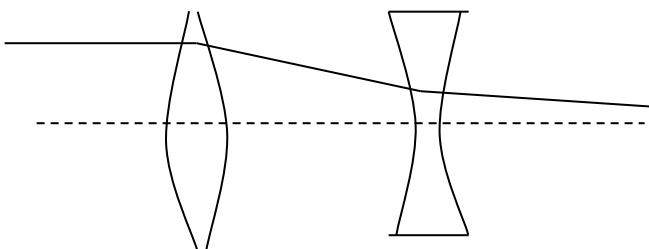

# What About the Other Plane?

$$f = -\frac{(B\rho)}{B'l}$$

Defocusing!

Luckily, if we place equal and opposite pairs of lenses, there will be a net focusing *regardless of the order*.

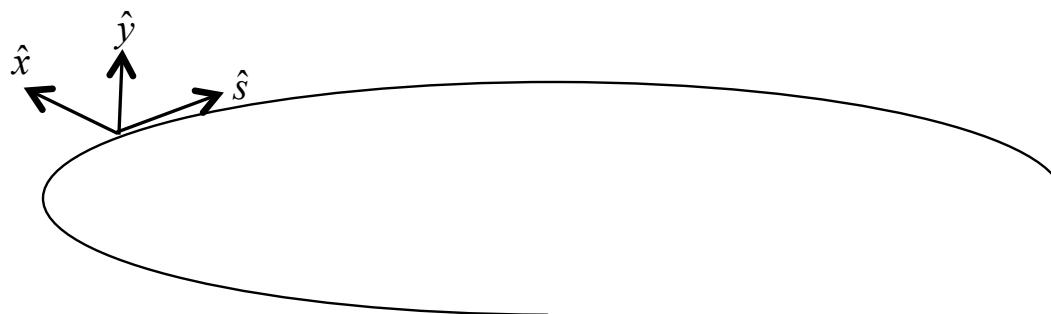

→pairs give net focusing in *both planes* -> “FODO cell”

# Formalism: Coordinates and Conventions

- We generally work in a right-handed coordinate system with  $x$  horizontal,  $y$  vertical, and  $s$  along the *nominal* trajectory ( $x=y=0$ ).

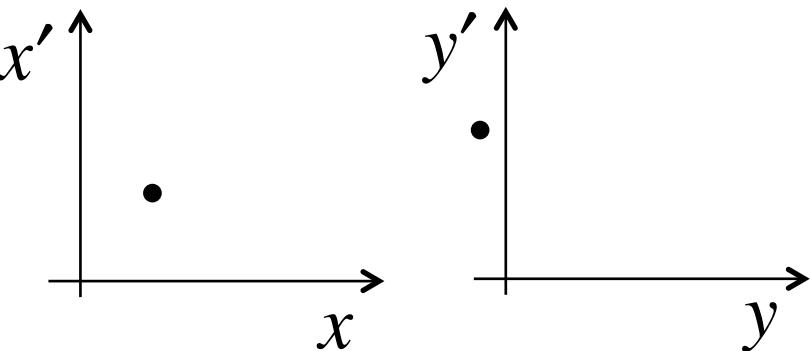

Note:  $s$  (rather than  $t$ ) is the independent variable

Particle trajectory defined at any point in  $s$  by location in  $x,x'$  or  $y,y'$  “phase space”

$$\frac{dx}{ds} \equiv x' \approx \theta$$

Diagram illustrating the derivative of position with respect to the independent variable  $s$ . A horizontal arrow points from  $x$  to  $x'$ , with a dashed line indicating the direction of motion. The label  $s \rightarrow$  is below the horizontal axis.

unique initial phase space point → unique trajectory

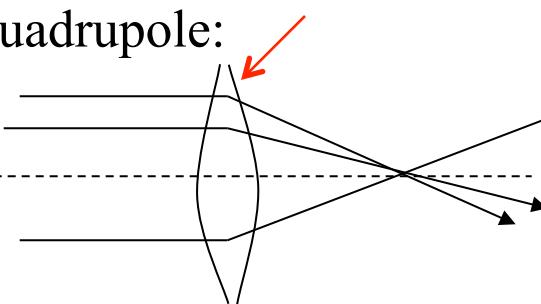

# Transfer Matrices

- Dipoles *define* the trajectory, so the simplest magnetic “lattice” consists of quadrupoles and the spaces in between them (drifts). We can express each of these as a linear operation in phase space.

$$\Delta\theta = \Delta x' = -\frac{x}{f}$$

Quadrupole:

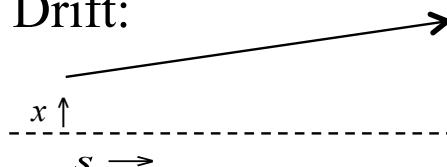

$$x = x(0)$$

$$x' = x'(0) - \frac{1}{f} x(0)$$

$$\Rightarrow \begin{pmatrix} x \\ x' \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ -\frac{1}{f} & 1 \end{pmatrix} \begin{pmatrix} x(0) \\ x'(0) \end{pmatrix}$$

Drift:

$$x(s) = x(0) + sx'(0)$$

$$x'(s) = x'(0)$$

$$\Rightarrow \begin{pmatrix} x(s) \\ x'(s) \end{pmatrix} = \begin{pmatrix} 1 & s \\ 0 & 1 \end{pmatrix} \begin{pmatrix} x(0) \\ x'(0) \end{pmatrix}$$

- By combining these elements, we can represent an arbitrarily complex ring or line as the product of matrices.

$$\mathbf{M} = \mathbf{M}_N \dots \mathbf{M}_2 \mathbf{M}_1$$

# Example: Transfer Matrix of a FODO cell

- At the heart of every beam line or ring is the basic “FODO” cell, consisting of a focusing and a defocusing element, separated by drifts:

Remember: motion is usually drawn from left to right, but matrices act from right to left!

$$\Rightarrow \mathbf{M} = \begin{pmatrix} 1 & L \\ 0 & 1 \end{pmatrix} \left( +\frac{1}{f} \quad 1 \right) \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \left( -\frac{1}{f} \quad 1 \right) = \begin{pmatrix} 1 - \frac{L}{f} - \left(\frac{L}{f}\right)^2 & 2L + \frac{L^2}{f} \\ -\frac{L}{f^2} & 1 + \frac{L}{f} \end{pmatrix}$$

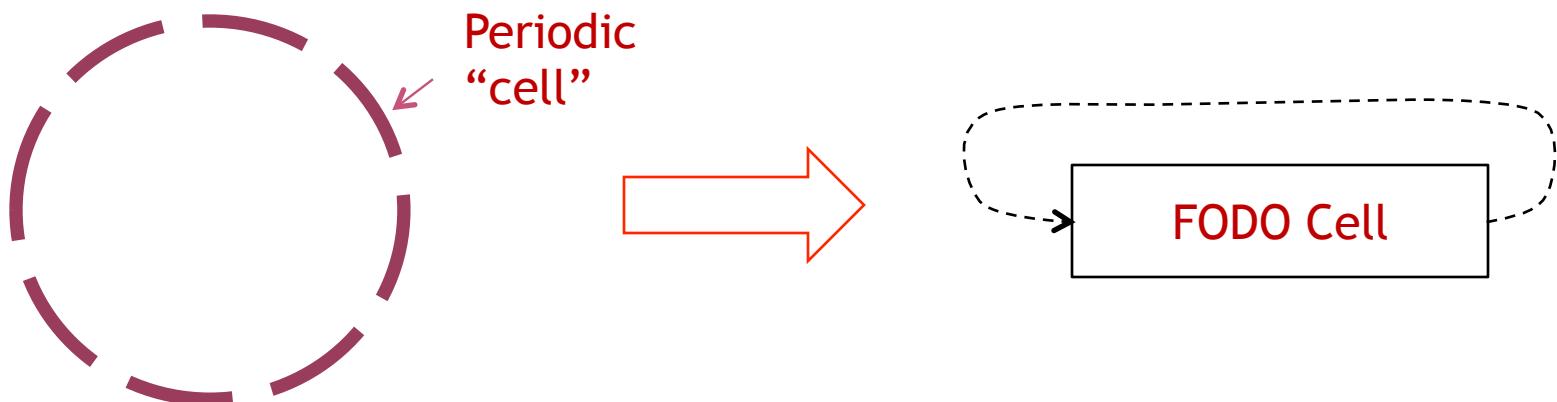

Sign of  $f$  flips in other plane

- Can build this up to describe any beam line or ring

# Periodic Systems

- You might think, “Start with a beam line, then make a ring out of it.”
  - Difficult to solve general case, because it depends on the initial conditions
- Therefore, we initially solve for stable motion in a *periodic system*
- We can think of a ring made of identical FODO cells as just the same cell, over and over.

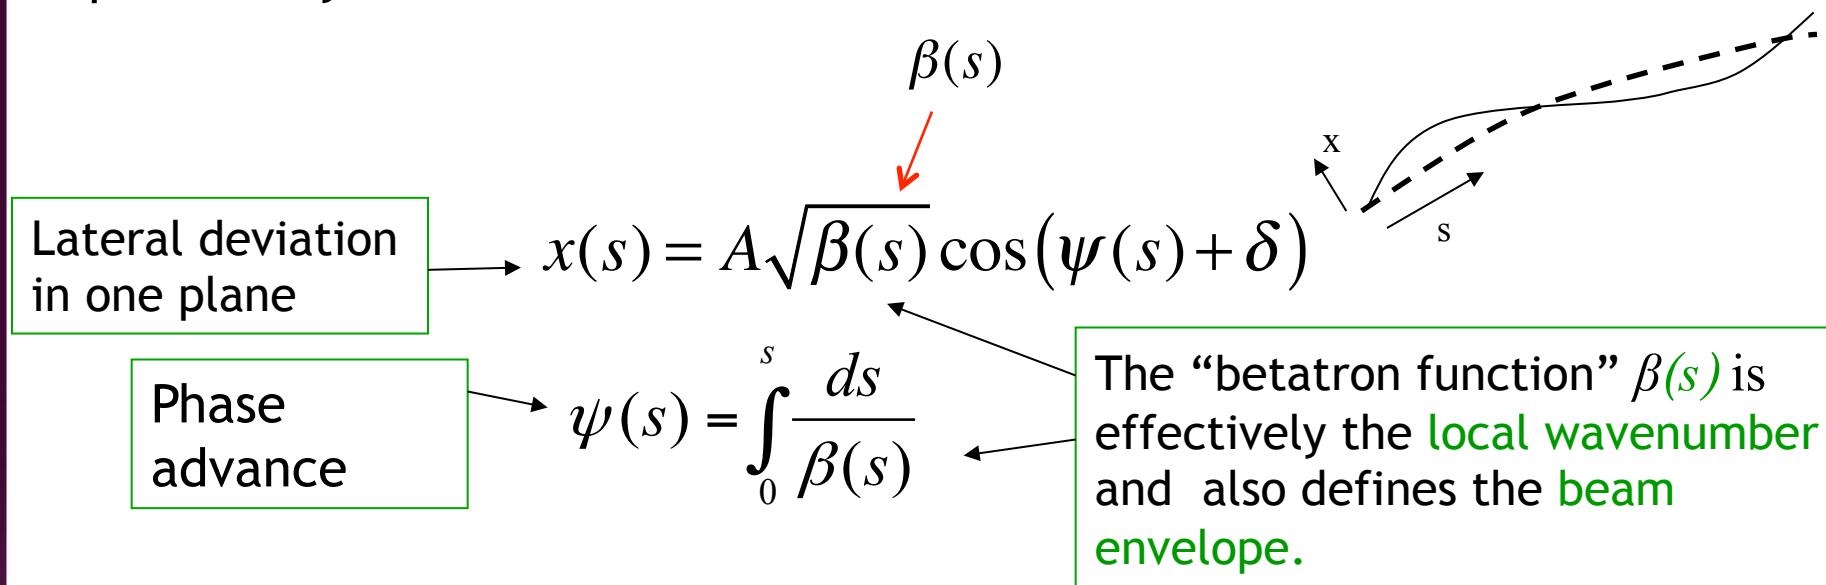

$$\mathbf{M}_{ring} = \mathbf{M}_{cell} \mathbf{M}_{cell} \cdots \mathbf{M}_{cell} = \mathbf{M}_{cell}^N$$

- Our goal is to decouple the problem into two parts
  - The “lattice”: a mathematical description of the machine itself, based only on the magnetic fields, *which is identical for each identical cell*
  - The “emittance”: mathematical description for the ensemble of particles circulating in the machine.
- Extend to beam lines by using boundary conditions (“matching”)

# General Solution: Betatron Motion

- We find (after a lot of algebra) that we can describe particle motion in terms of initial conditions and a “beta function”  $\beta(s)$ , which is only a function of location along the nominal path, and follows the periodicity of the machine.

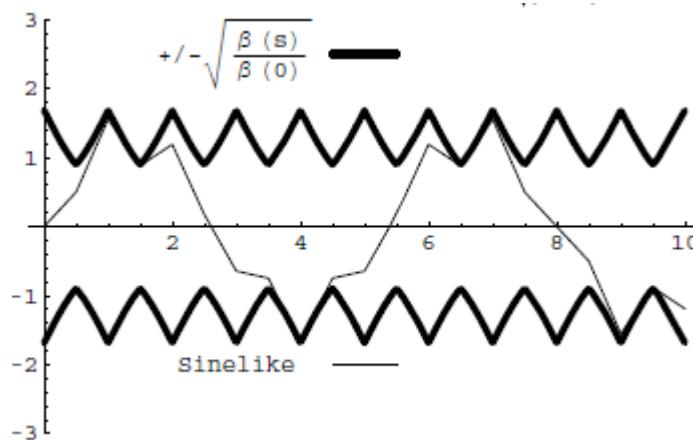

- In other words, particles undergo “pseudo-harmonic” motion about the nominal trajectory, with a variable wavelength.
- Note:  $\beta$  has units of [length], so the amplitude has units of [length] $^{1/2}$

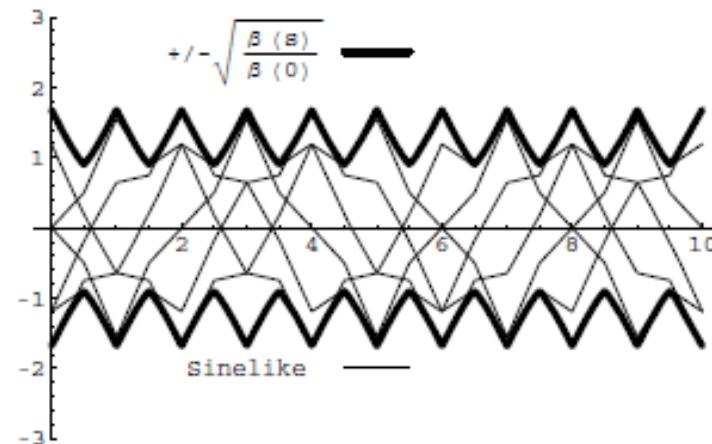

# Conceptual Understanding of $\beta$

- It's important to remember that the betatron function represents a *bounding envelope* to the beam motion, not the beam motion itself

Normalized particle trajectory

Trajectories over multiple turns (or trajectories of multiple particles!)

$$x(s) = A[\beta(s)]^{1/2} \sin(\psi(s) + \delta)$$

$$\psi(s) = \int_0^s \frac{ds}{\beta(s)}$$

$\beta(s)$  is also effectively the local wave number which determines the rate of phase advance

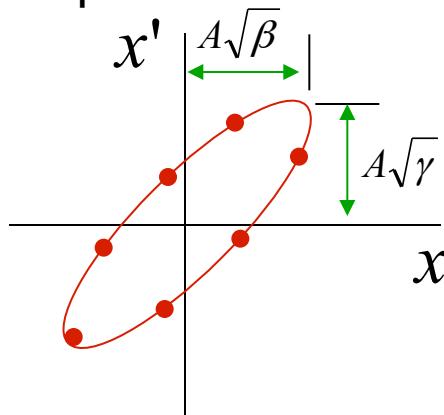

Closely spaced strong quads  $\rightarrow$  small  $\beta$   $\rightarrow$  small aperture, lots of wiggles

Sparingly spaced weak quads  $\rightarrow$  large  $\beta$   $\rightarrow$  large aperture, few wiggles

# Characterizing Particle Ensembles: Emittance

- A particle returning to the same point over many terms traces an ellipse, defined by the “beta function”,  $\beta$ , and two additional lattice parameters,  $\alpha$  and  $\gamma$ .

$$\beta x'^2 + 2\alpha x x' + \gamma x^2 = A^2 = \text{constant}$$

$$\alpha = -\frac{1}{2} \frac{d\beta}{ds}$$

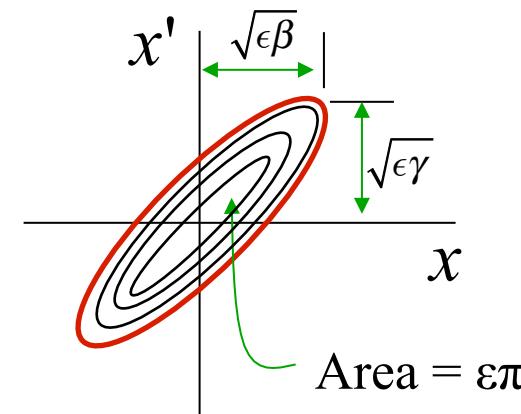

$$\gamma = \frac{1+\alpha^2}{\beta}$$

NOT to be confused with relativistic  $\beta$  and  $\gamma$ !

- An ensemble of particles can characterized by a bounding ellipse, known as the “emittance”
- Definitions vary: RMS, 95%, 99%, etc

$$\beta x'^2 + 2\alpha x x' + \gamma x^2 = \epsilon$$

Units of length

# Emittance, Beam Size, and Adiabatic Damping

- If we use the Gaussian definition emittance, then the beam size is

$$\sigma_x = \sqrt{\beta_x \epsilon}$$

- Emittance is constant at a constant energy, but as particles accelerate, the emittance decreases

$$\epsilon \propto \frac{1}{\beta \gamma}$$

Relativistic  $\beta$  and  $\gamma$   
(yes, I know it's confusing)

- This is known as “adiabatic damping”. We therefore define a “normalized emittance”

$$\epsilon_N \equiv \beta \gamma \epsilon$$

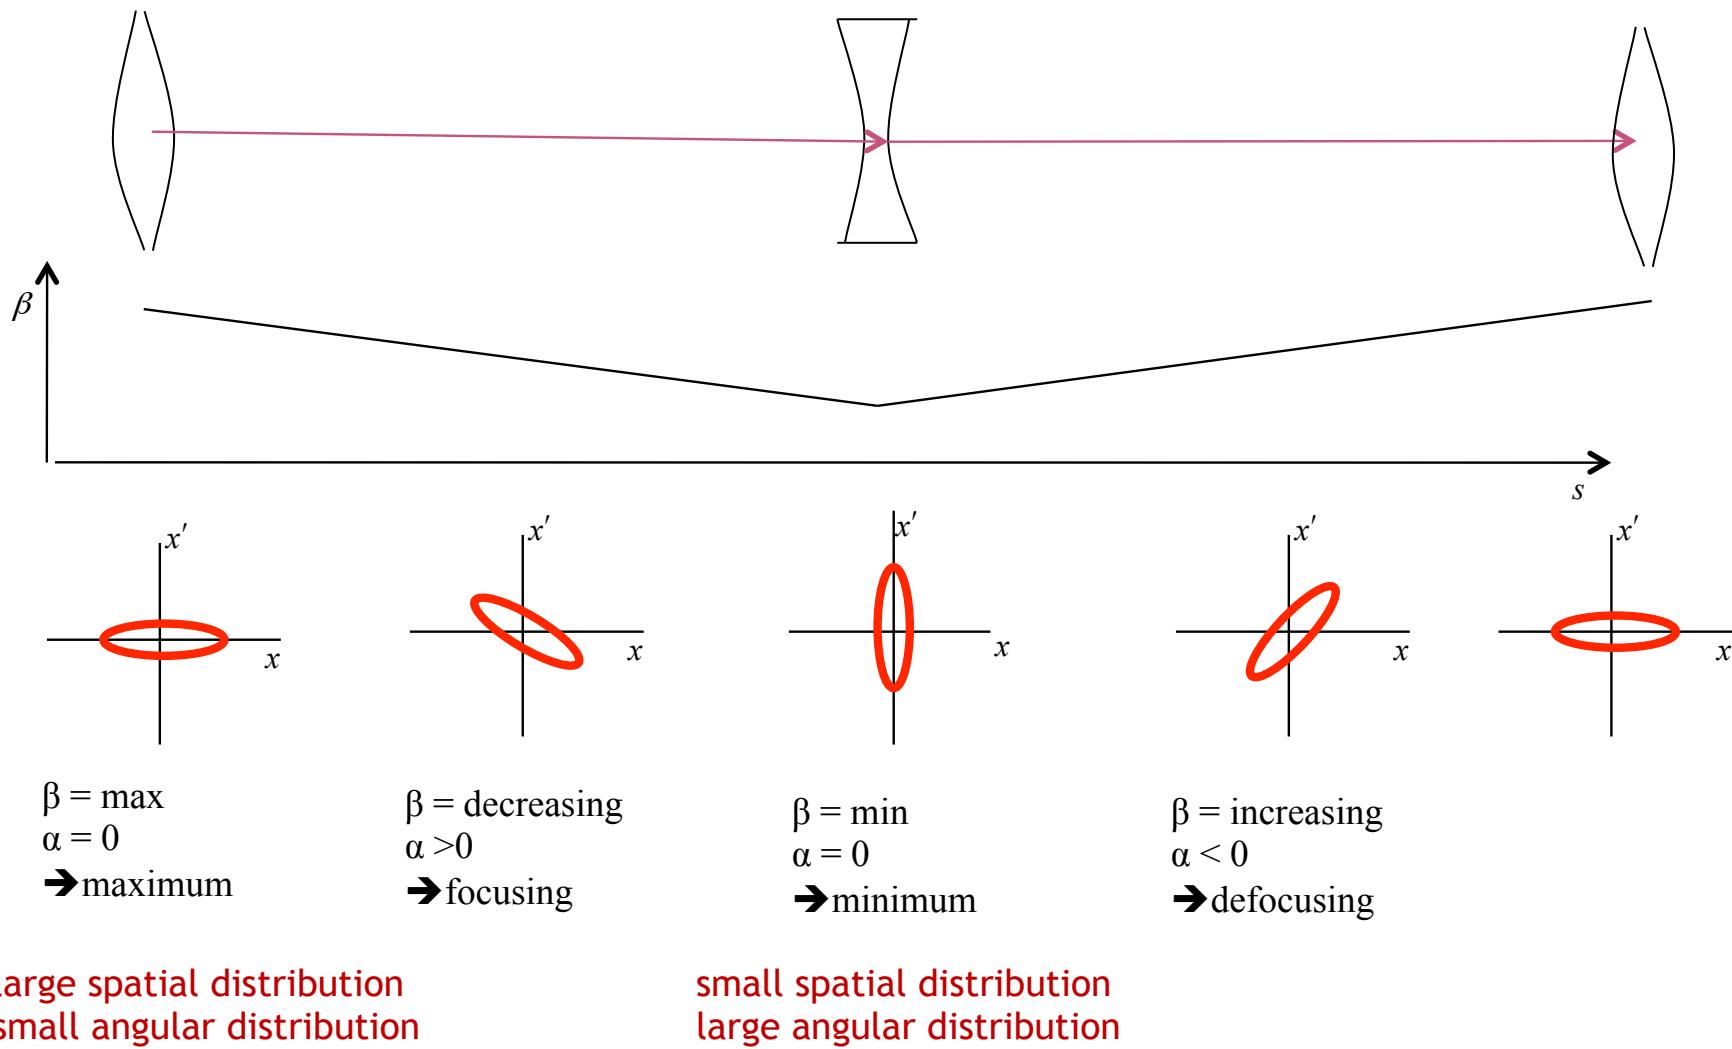

- which is constant with energy. Thus, at a particular energy

$$\sigma_x = \sqrt{\frac{\beta_x \epsilon_N}{\beta \gamma}} \propto \frac{1}{\sqrt{p}}$$

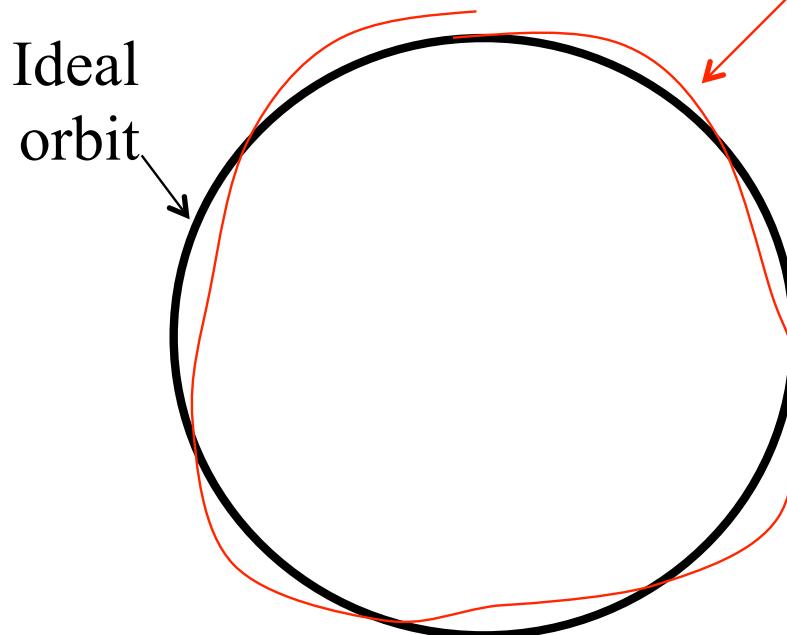

# Emittance and Beam Distributions

- As we go through a lattice the shape in phase space varies, but the bounding emittance remains constant

# Betatron Tune

Particle trajectory

- As particles go around a ring, they will undergo a number of betatrons oscillations  $\nu$  (sometimes  $Q$ ) given by

$$\nu = \frac{1}{2\pi} \oint \frac{ds}{\beta(s)}$$

- This is referred to as the “tune”

- We can generally think of the tune in two parts:

Integer : magnet/  
aperture  
optimization

→ 6.7 ←

Fraction:  
Beam Stability

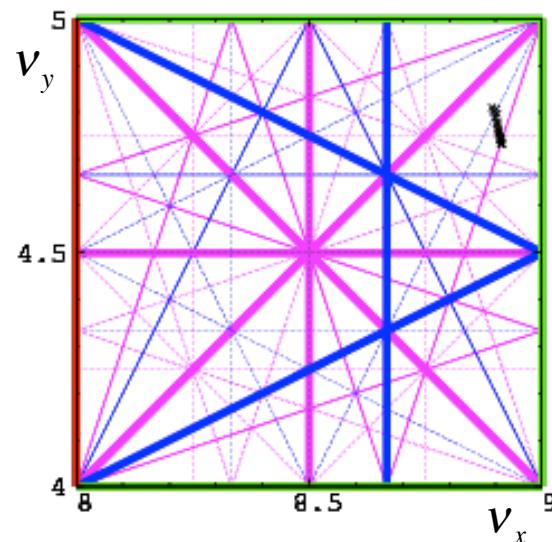

# Tune, Stability, and the Tune Plane

- If the tune is an integer, or low order rational number, then the effect of any imperfection or perturbation will tend be reinforced on subsequent orbits.
- When we add the effects of coupling between the planes, we find this is also true for *combinations* of the tunes from both planes, so in general, we want to avoid

$$k_x \nu_x \pm k_y \nu_y = \text{integer} \Rightarrow (\text{resonant instability})$$

↑  
“small” integers

→ Avoid lines in  
the “tune plane”

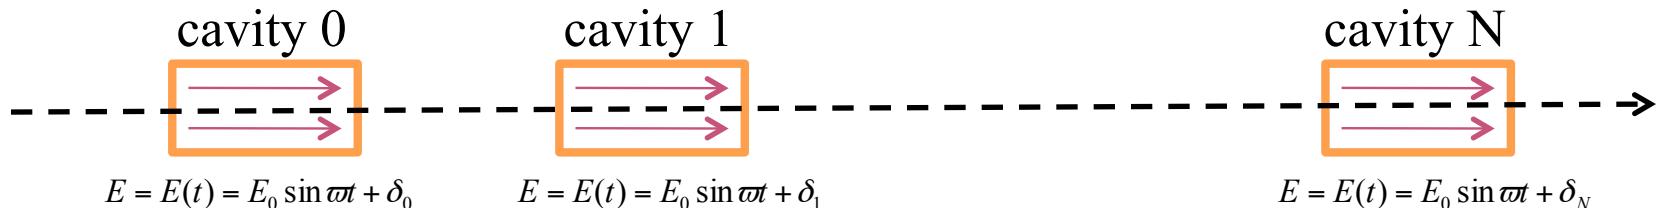

- Many instabilities occur when something perturbs the tune of the beam, or part of the beam, until it falls onto a resonance, thus you will often hear effects characterized by the “tune shift” they produce.
  - For example: the maximum tune shift sets the absolute luminosity limit in a collider

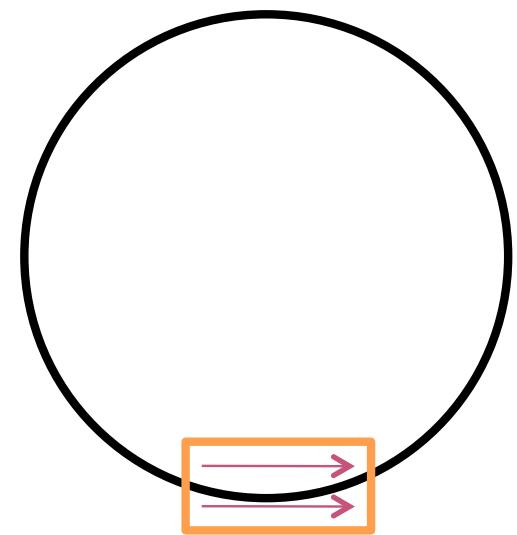

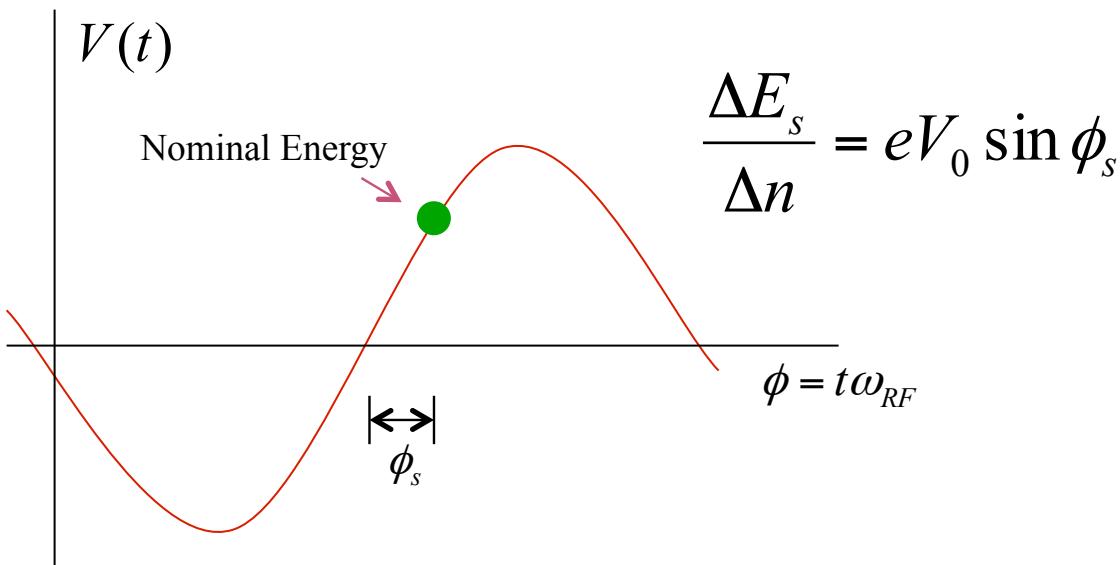

# Longitudinal Motion

- We will generally accelerate particles using structures that generate time-varying electric fields (RF cavities), either in a linear arrangement

or located within a circulating ring

- In both cases, we want to phase the RF so a nominal arriving particle will see the same accelerating voltage and therefore get the same boost in energy

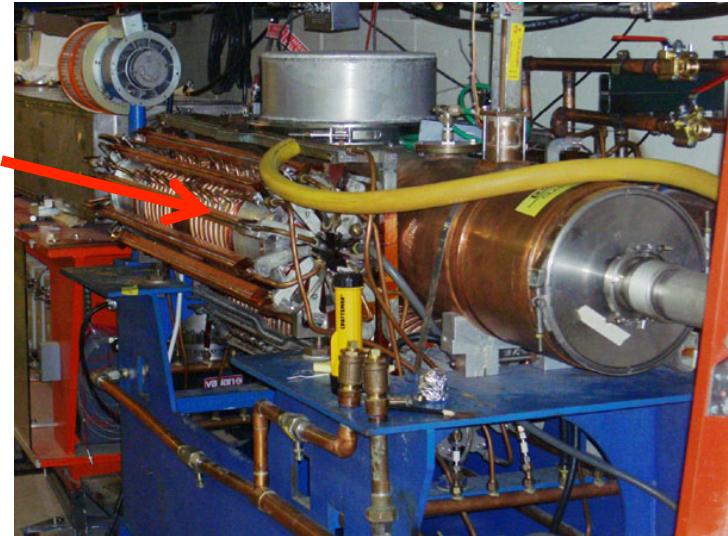

# Examples of Accelerating RF Structures

Fermilab Drift Tube Linac  
(200MHz): oscillating field  
uniform along length

Biased ferrite  
frequency tuner

37->53MHz Fermilab Booster cavity

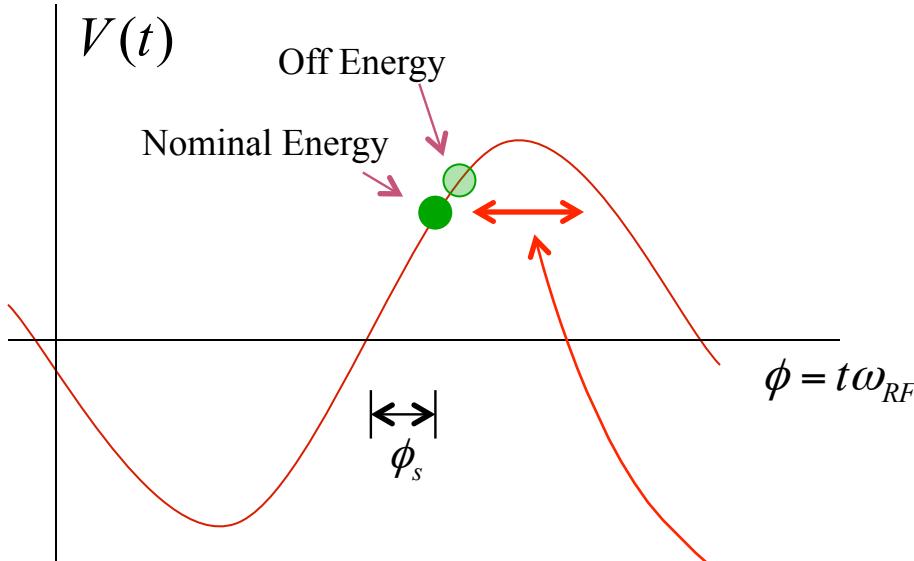

ILC prototype elliptical cell “ $\pi$ -cavity” (1.3 GHz): field alternates with each cell

# Phase Stability

- A particle with a slightly different energy will arrive at a slightly different time, and experience a slightly different acceleration

$$\frac{\Delta\tau}{\tau} = \eta \frac{\Delta p}{p}$$

“slip factor” = dependence of period on momentum  
- negative for linacs  
- positive for (relativistic) cyclotrons  
- goes from negative to positive in synchrotrons (“transition”)  
Stable point depends on sign.

- Longitudinal motion about stable phase referred to as “synchrotron motion”.

- Takes many revolutions to complete one longitudinal cycle in a synchrotron, so multiple RF cavities are just seen as a vector sum.

# Some Important Early Synchrotrons

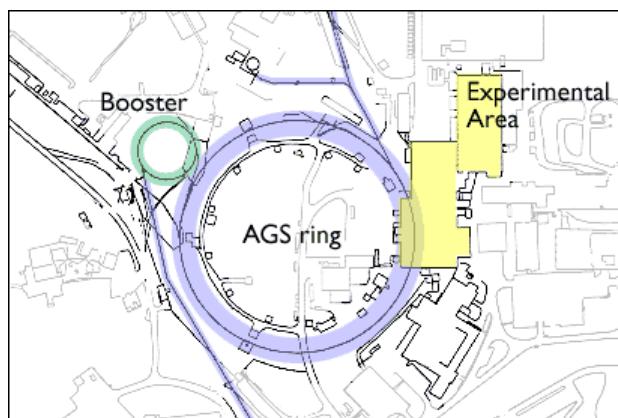

## Berkeley Bevatron,

- 1954 (weak focusing)
- 6.2 GeV protons
- Discovered antiproton

## CERN Proton Synchrotron (PS)

- 1959
- 628 m circumference
- 28 GeV protons
- Still used in LHC injector chain!

The Alternating Gradient Synchrotron complex

## Brookhaven Alternating Gradient Synchrotron (AGS)

- 1960
- 808 m circumference
- 33 GeV protons
- Discovered charm quark, CP violation, muon neutrino

# Getting the Most Energy: The Case for Colliders

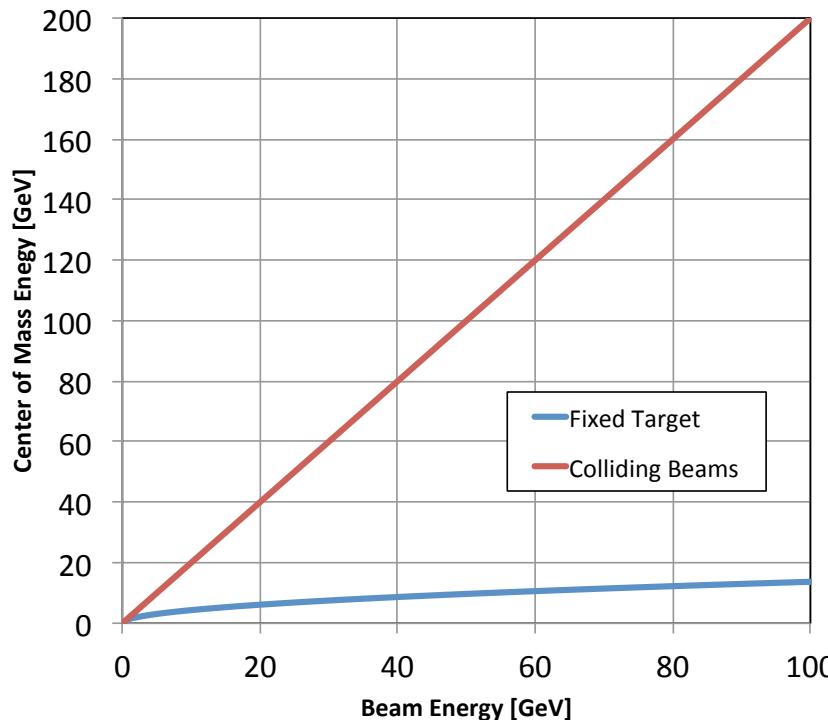

- If beam hits a stationary proton, the “center of mass” energy is

$$E_{CM} = \sqrt{2E_{beam}m_{target}c^2}$$

- On the other hand, for colliding beams (of equal mass and energy) it's

$$E_{CM} = 2E_{beam}$$

- To get the 14 TeV CM design energy of the LHC with a single beam on a fixed target would require that beam to have an energy of 100,000 TeV!

*• Would require a ring 10 times the diameter of the Earth!!*

**Getting to the highest energies requires colliding beams**

# Luminosity

The relationship of the beam to the rate of observed physics processes is given by the “Luminosity”

$$\text{Rate} \rightarrow R = L\sigma$$

“Luminosity”                          Cross-section (“physics”)

Standard unit for Luminosity is  $\text{cm}^{-2}\text{s}^{-1}$

Standard unit of cross section is “barn” =  $10^{-24} \text{ cm}^2$

Integrated luminosity is usually in  $\text{barn}^{-1}$ , where

$$\text{b}^{-1} = (1 \text{ sec}) \times (10^{24} \text{ cm}^{-2}\text{s}^{-1})$$

$$\text{nb}^{-1} = 10^9 \text{ b}^{-1}, \text{ fb}^{-1} = 10^{15} \text{ b}^{-1}, \text{ etc}$$

For (thin) fixed target:

$$R = N\rho_n t \sigma \Rightarrow L = N\rho_n t$$

Target thickness

Incident rate

Target number density

Example: MiniBooNe primary target:

$$L \approx 10^{37} \text{ cm}^{-2}\text{s}^{-1}$$

# Luminosity of Colliding Beams

- For equally intense Gaussian beams

Collision frequency

$$L = f \frac{N_b^2}{4\pi\sigma^2} R$$

Particles in a bunch

Geometrical factor:  
 - crossing angle  
 - hourglass effect

Transverse size (RMS)

- Using  $\sigma^2 = \frac{\beta^* \epsilon_N}{\beta \gamma} \approx \frac{\beta^* \epsilon_N}{\gamma}$  we have

$$L = f_{rev} \frac{1}{4\pi} n N_b^2 \frac{\gamma}{\beta^* \epsilon_N} R$$

↑ prop. to energy  
↑ Normalized emittance  
↑ Betatron function at collision point → want a small  $\beta^*$ !

Revolution frequency

Number of bunches

Particles in bunch

Record e+e- Luminosity (KEK-B):

$2.11 \times 10^{34} \text{ cm}^{-2}\text{s}^{-1}$

Record p-pBar Luminosity (Tevatron):

$4.06 \times 10^{32} \text{ cm}^{-2}\text{s}^{-1}$

Record Hadronic Luminosity (LHC):

$7.0 \times 10^{33} \text{ cm}^{-2}\text{s}^{-1}$

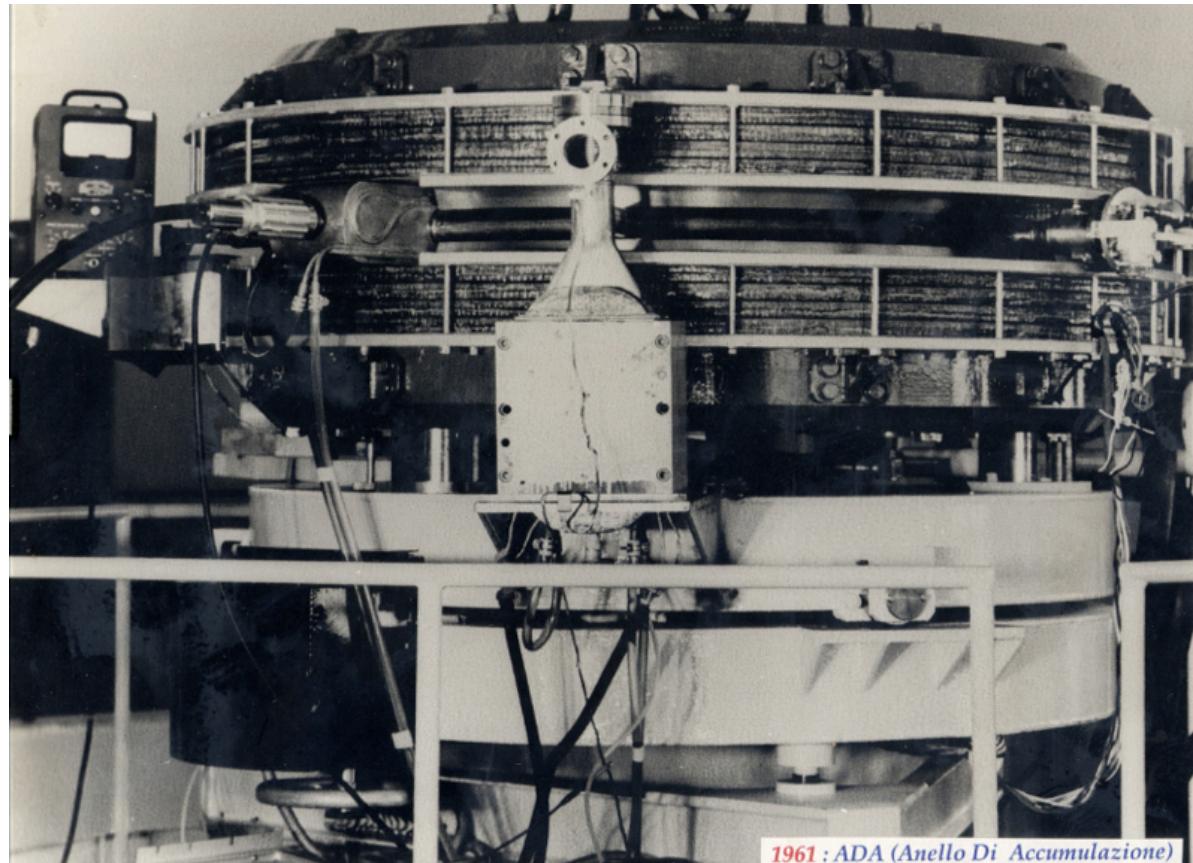

LHC Design Luminosity:

$1.00 \times 10^{34} \text{ cm}^{-2}\text{s}^{-1}$

# First $e^+e^-$ Collider

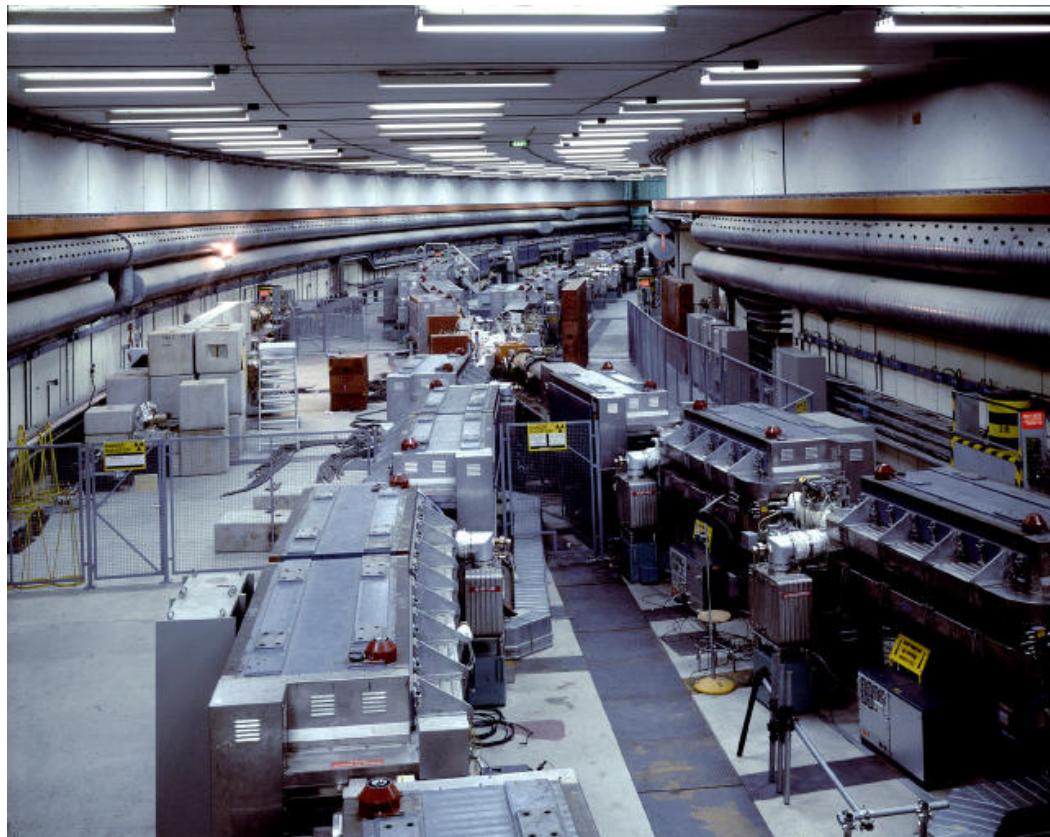

- ADA (Anello Di Accumulazione) at INFN, Frascati, Italy (1961)
  - 250 MeV  $e^+$  x 250 MeV  $e^-$

- It's easier to collide  $e^+e^-$ , because synchrotron radiation naturally “cools” the beam to smaller size.

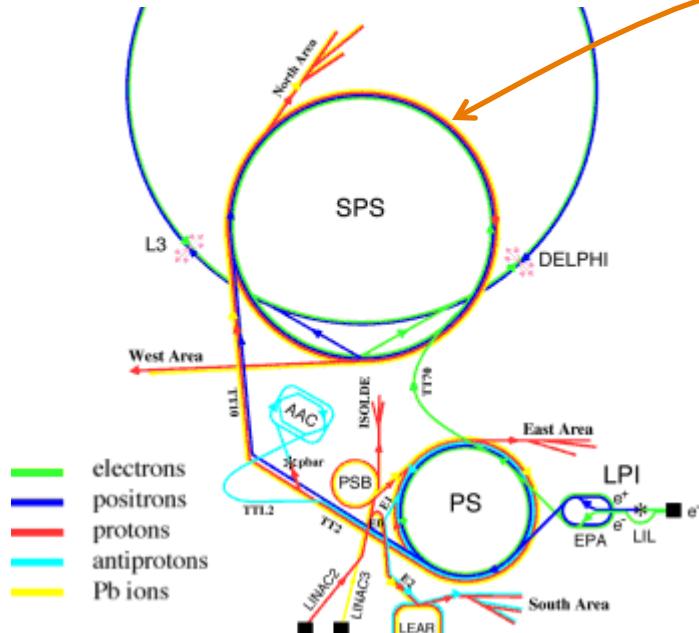

# First Proton Collider: CERN Intersecting Storage Rings (ISR)

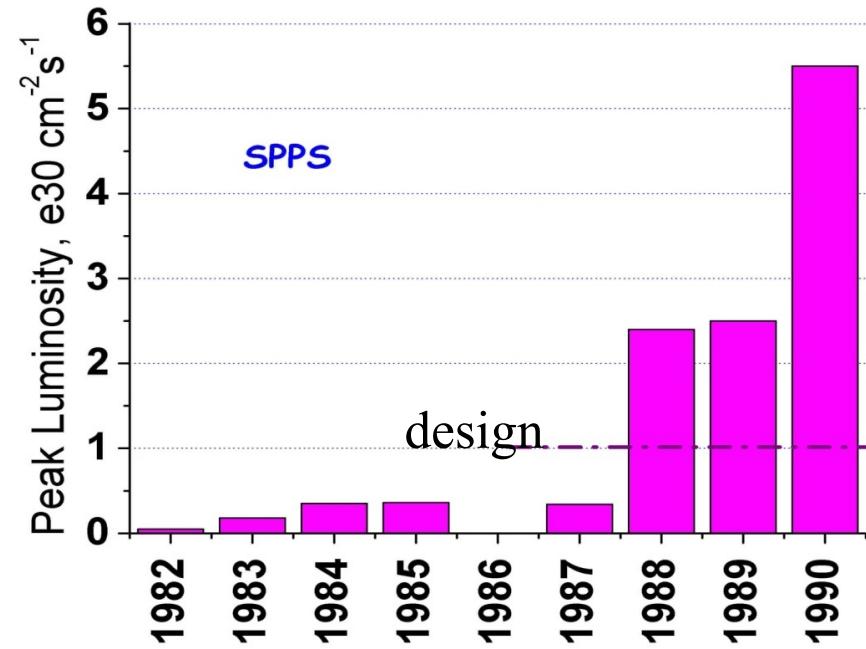

- 1971
- 31 GeV + 31 GeV colliding proton beams.
  - Highest CM Energy for 10 years
- Set a luminosity record that was not broken for 28 years!

# SppS: First Proton-Antiproton Collider

- Energy initially 270+270 GeV
- Raised to 315+315 GeV
  - Limited by power loss in magnets!

- Protons from the **SPS** were used to produce antiprotons, which were collected
- These were injected in the opposite direction (same beam pipe) and accelerated
- First collisions in 1981
- Discovery of W and Z in 1983
  - Nobel Prize for Rubbia and Van der Meer

# Superconductivity: Enabling Technology

- The maximum  $S_{ppS}$  energy was limited by the maximum power loss that the conventional magnets could support.
  - LHC made out of such magnets would be roughly the size of Rhode Island!
- Highest energy colliders only possible using superconducting magnets
- Must take the bad with the good
  - Conventional magnets are simple and naturally dissipate energy as they operate

Superconducting magnets are complex and represent a great deal of stored energy which must be handled if something goes wrong

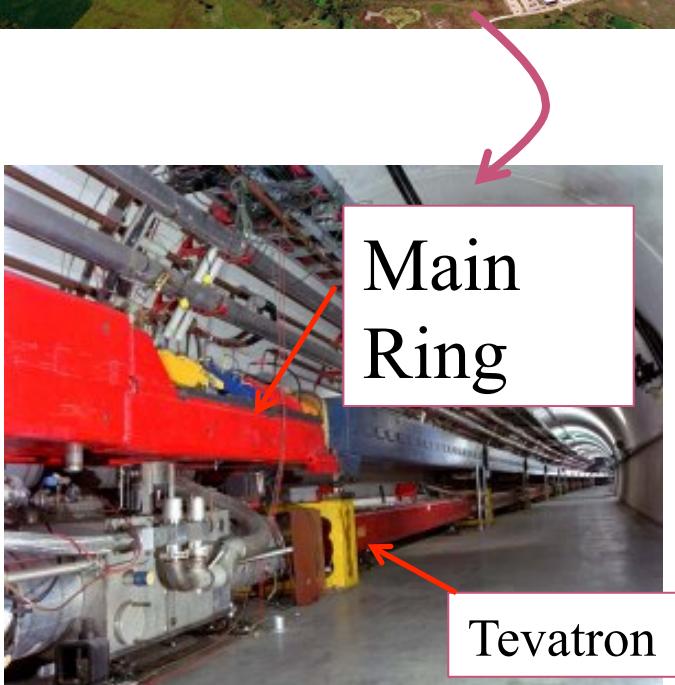

$$E \propto B^2$$

- R&D into superconducting technology is absolutely critical in the quest for the highest energies (made Tevatron and LHC possible!)
- Machine protection is one of the biggest challenges.

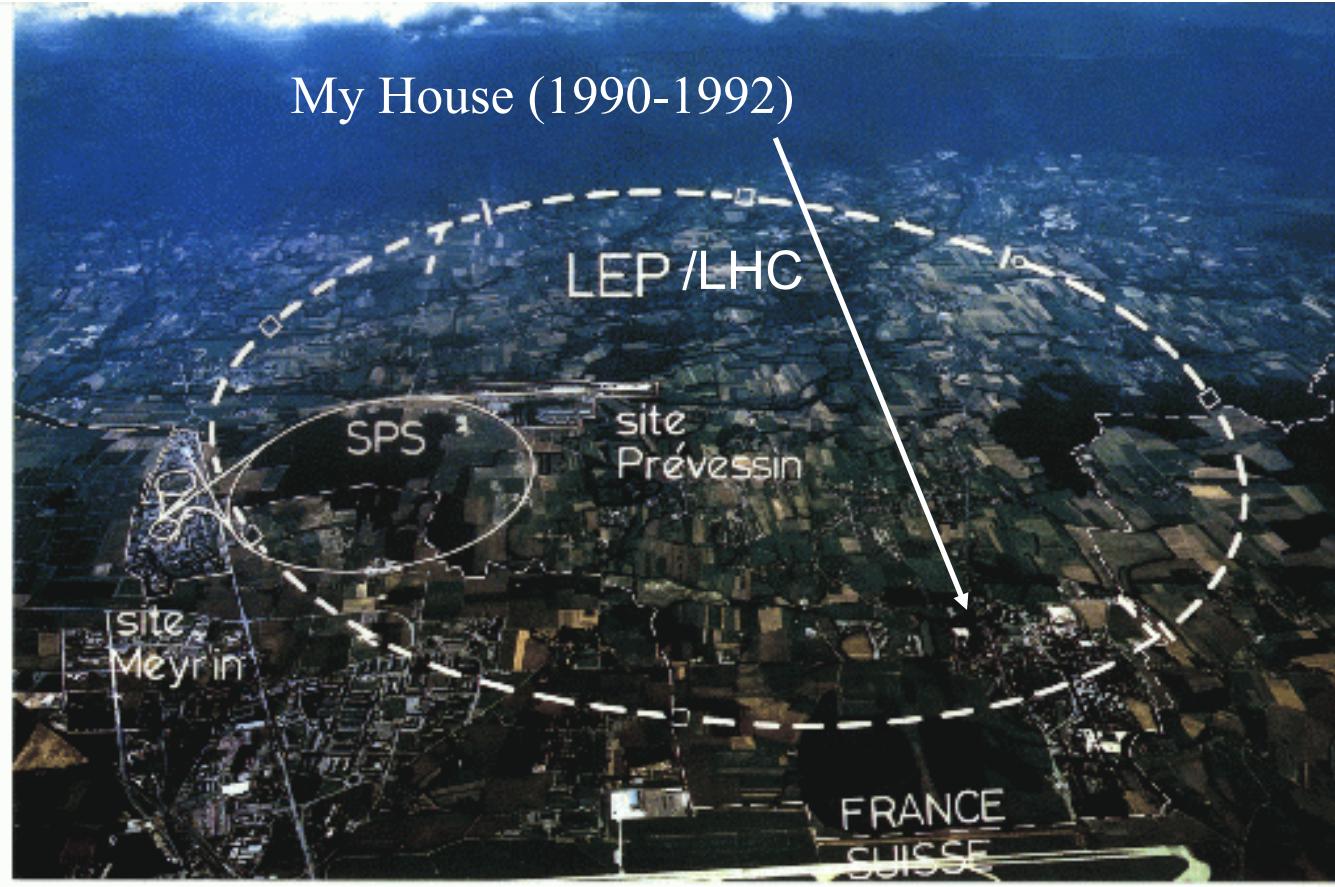

# Tevatron: First Superconducting Synchrotron

- 1968 - Fermilab Construction Begins
- 1972 - Beam in Main Ring
  - (normal magnets)
- Plans soon began for a superconducting collider to share the ring.
  - Dubbed “Saver Doubler”  
**(later “Tevatron”)**
- 1985 - First proton-antiproton collisions in Tevatron
  - Most powerful accelerator in the world *for the next quarter century*
- 1995 - Top quark discovery
- 2011 - Tevatron shut down after successful LHC startup

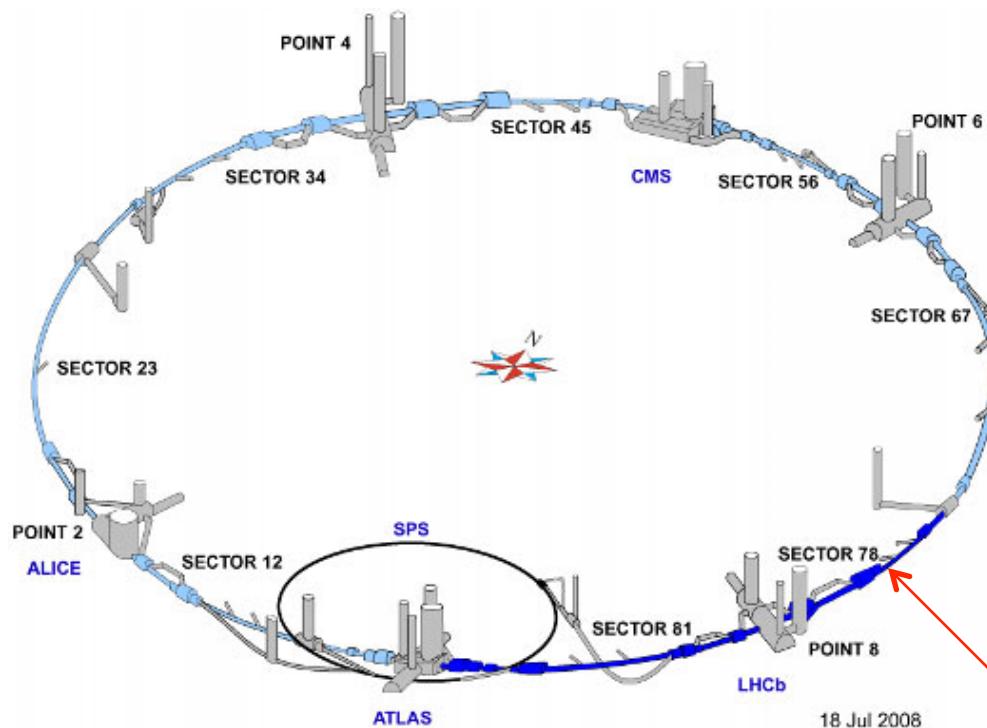

# Back the present: Large Hadron Collider

- Straddles French/Swiss border near Geneva, Switzerland
- Tunnel originally dug for LEP
  - Built in 1980's as an electron positron collider
  - Max 100 GeV/beam, but 27 km in circumference!!

# LHC Layout and Numbers

- 27 km in circumference
- 2 major collision regions: CMS and ATLAS
- 2 “smaller” regions: ALICE and LHCb

## Design:

- 7 TeV+7 TeV proton beams
  - 7 times Fermilab Tevatron
  - Magnets have two beam pipes, one going in each direction.
- Stored beam energy 150 times more than Tevatron
  - Each beam has only  $5 \times 10^{-10}$  grams of protons, but has the energy of a train going 100 mph!!
- These beams are focused to a size *smaller than a human hair* to collide with each other!

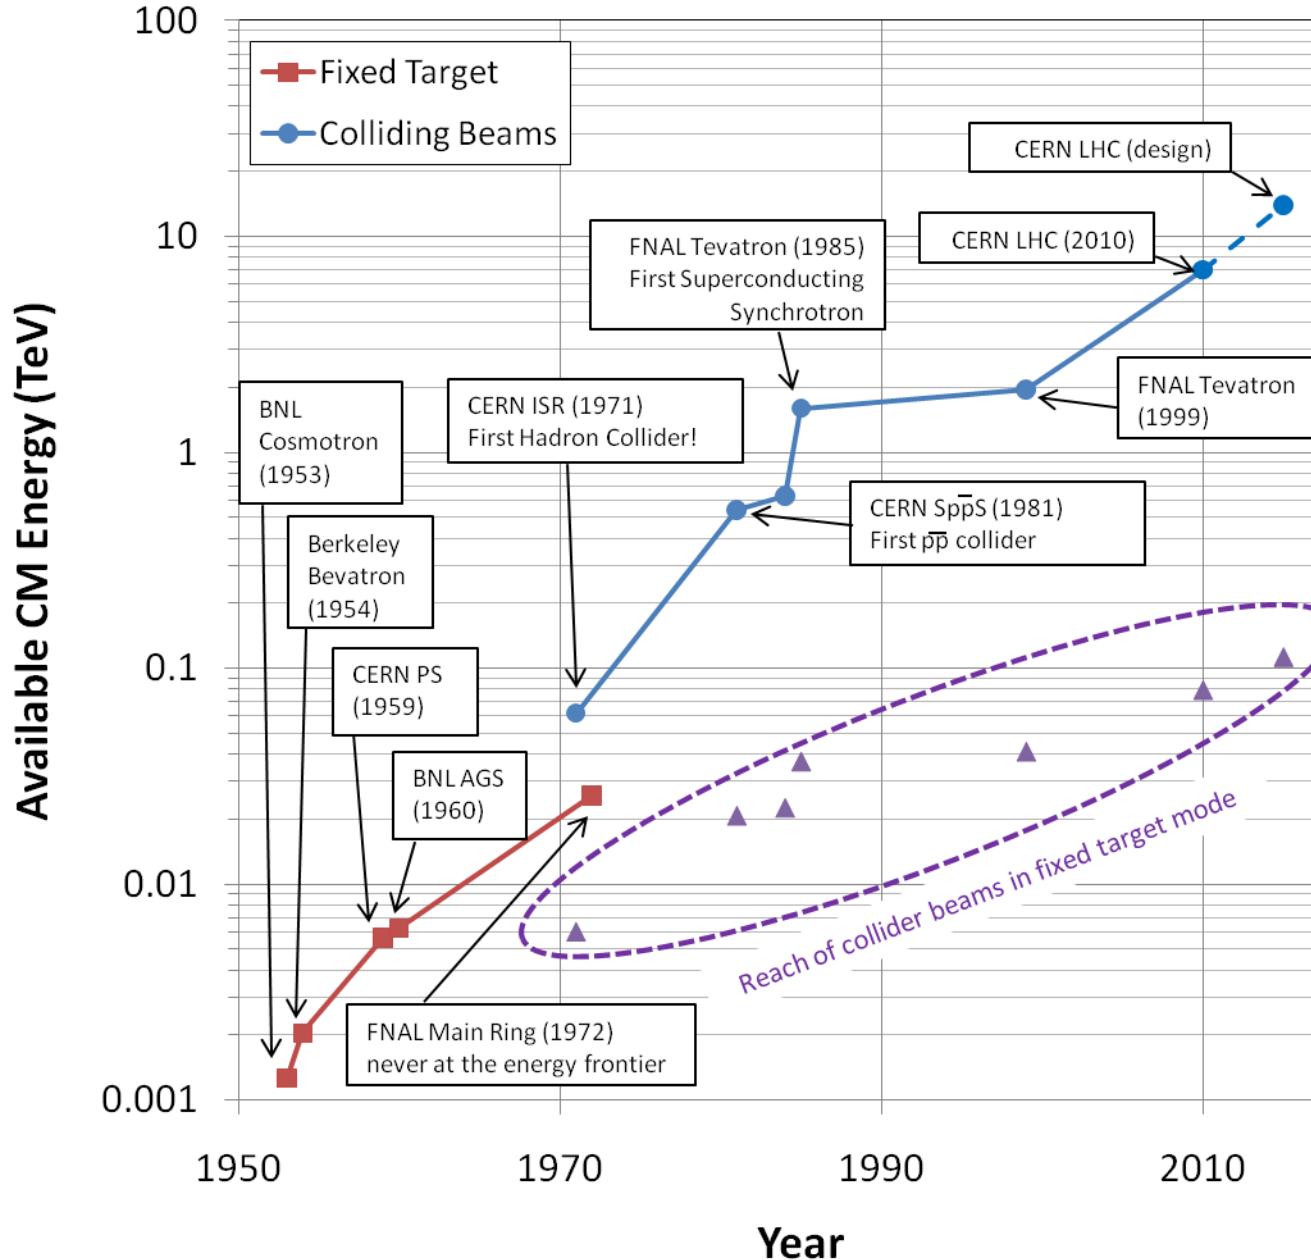

# Partial LHC Timeline

- 2008
  - September 10<sup>th</sup>: First circulating beam
  - September 19<sup>th</sup>: BAD accident brings beam down for over a year (remember what I said about machine protection!)
- 2009
  - November 20<sup>th</sup>: Particles circulate again
- 2010
  - March 30<sup>th</sup>: 3.5 + 3.5 TeV collisions
    - Energy limited by flaw which caused accident
- 2012
  - April 5<sup>th</sup>: Energy increased to 4 + 4 TeV
  - July 4<sup>th</sup>: Announced the discovery of the Higgs
- 2013
  - Feb. 14<sup>th</sup>: Start 2 year shutdown to address design flaw and allow full energy operation
- 2015
  - Mar. 7: protons injected
  - May 20: 6.5+6.5 TeV protons collided

The LHC will (probably) be the flagship of the Energy Frontier for at least the next 20 years!

# Evolution of the Accelerator Energy Frontier

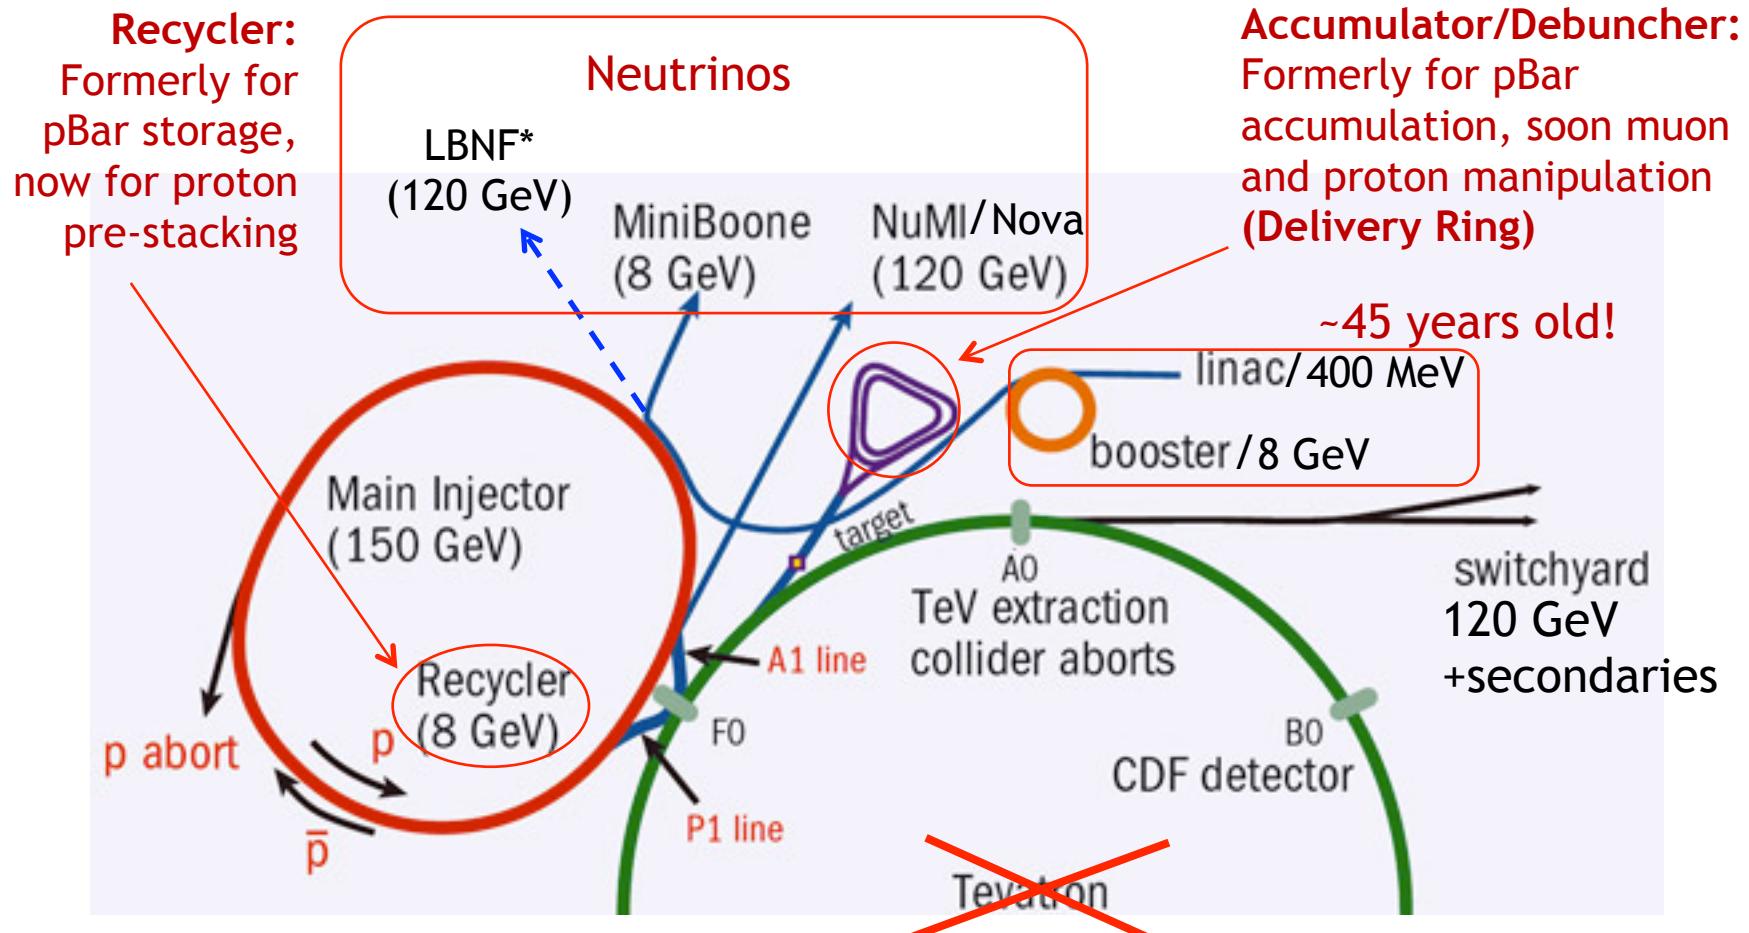

~a factor of  
10 every 15  
years

That trend  
will not  
continue

# Fermilab Accelerator Complex Today

- As LHC takes over the Energy Frontier, Fermilab focuses on intensity-based physics

\*proposed

# Possible Future Accelerators

## ○ Circular Hadron Colliders

- “Future Circular Collider”: 100 km 50+50 TeV proton collider, based at CERN

## ○ Linear $e^+e^-$ colliders

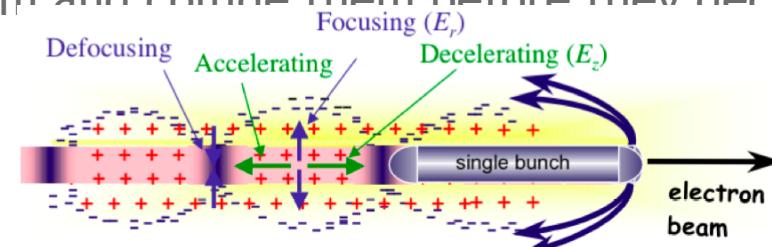

- “International Linear Collider” (ILC): Up to 500+500 GeV  $e^+e^-$  collider
  - Not energy frontier!
- “Compact Linear Collider” (CLIC): Up to 1.5 TeV+1.5 TeV  $e^+e^-$  collider

## ○ Muon collider?

- Muons are point-like, like electrons, but don’t radiate as much (good)
- but they are unstable (bad)
- R&D to find a way to cool them and collide them before they decay
- Up to 5 TeV+5 TeV  $\mu^+\mu^-$

## ○ Even more exotic?

- Plasma wakefield?
- Dielectric wakefield?
- Huge fields, but also huge technical challenges

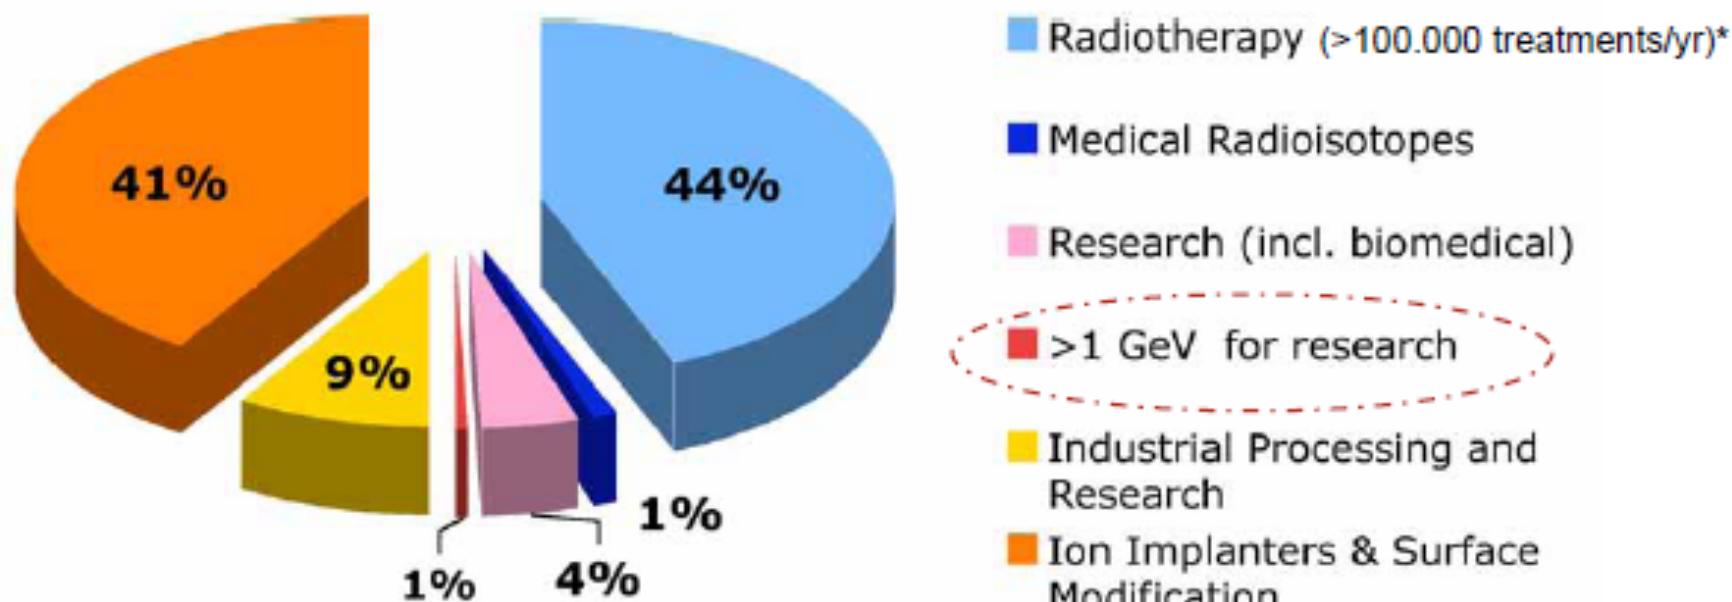

# Research Machines: Just the Tip of the Iceberg

## Number of accelerators worldwide

~ 26,000

*Annual growth is several percent*

*Sales >3.5 B\$/yr*

*Value of treated good > 50 B\$/yr \*\**

# Example: Spallation Neutron Source (Oak Ridge, TN)

A 1 GeV Linac loads  $1.5\text{E}14$  protons into a non-accelerating synchrotron ring.

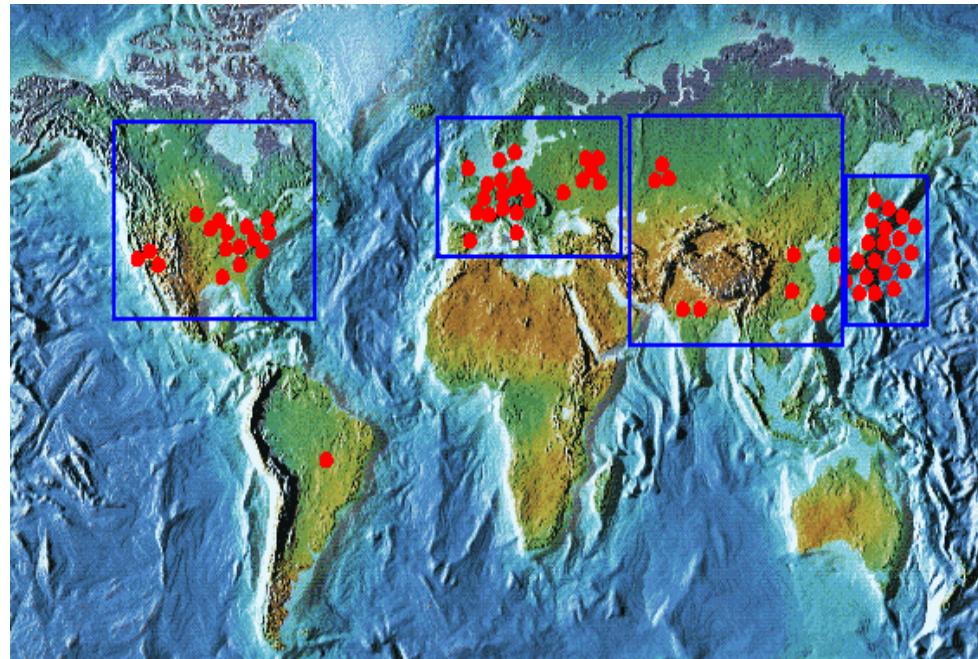

These are fast extracted onto a Mercury target

This happens at 60 Hz  $\rightarrow 1.4\text{ MW}$

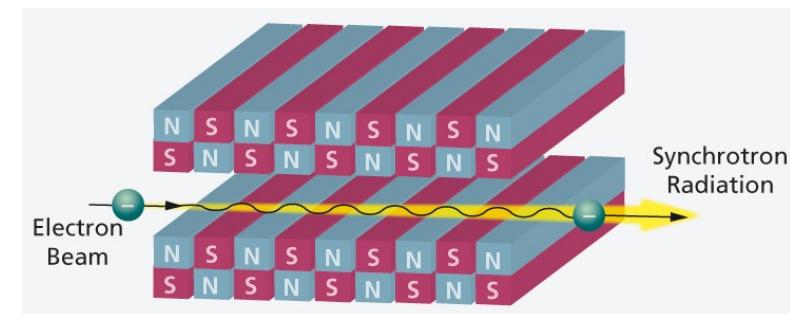

Neutrons are used for biophysics, materials science, industry, etc...

# Light sources: too many to count

- Put circulating electron beam through an “undulator” to create synchrotron radiation (typically X-ray)
- Many applications in biophysics, materials science, industry.
- New proposed machines will use very short bunches to create coherent light.

# Other uses of accelerators

- Radioisotope production
- Medical treatment
- Electron welding
- Food sterilization
- Catalyzed polymerization
- Even art...

In a “Lichtenberg figure”, a low energy electron linac is used to implant a layer of charge in a sheet of lucite. This charge can remain for weeks until it is discharged by a mechanical disruption.

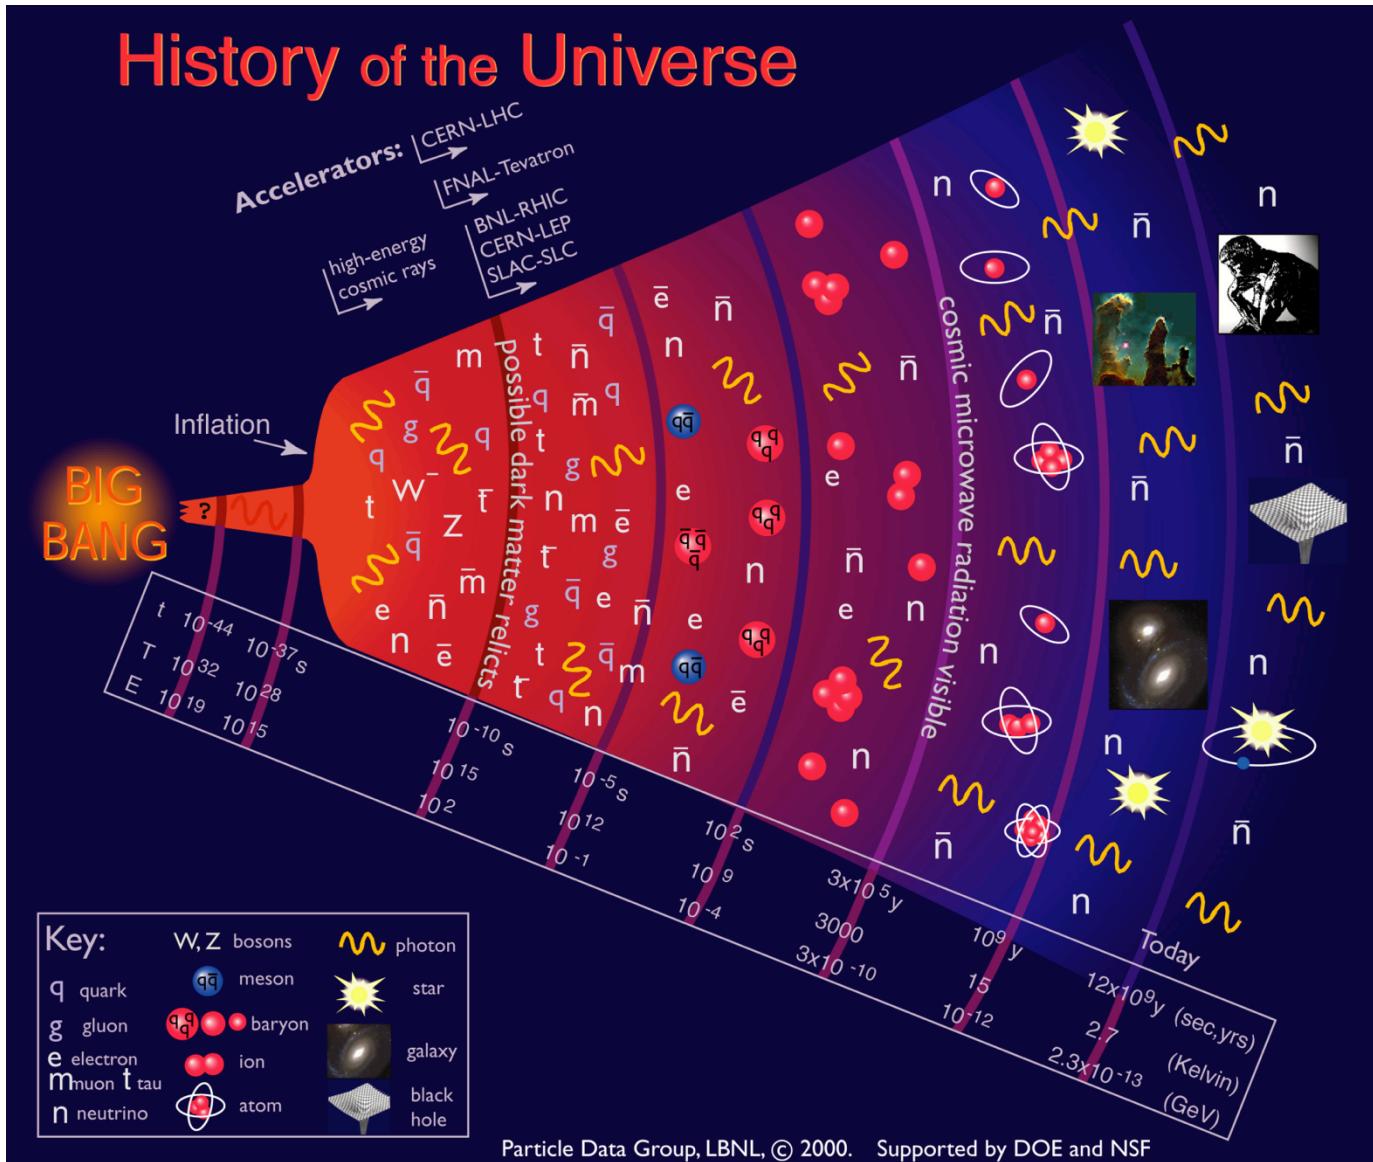

# Further Reading (in Order of Increasing Depth)

- My lectures at the 2014 Hadron Collider Physics Summer School
  - More details about Fermilab and the LHC (including “The Incident”)
  - <http://tinyurl.com/prebys-hcpss-2014>
- Fermilab “Accelerator Concepts” (“Rookie Book”)
  - [http://www-bdnew.fnal.gov/operations/rookie\\_books/Concepts\\_v3.6.pdf](http://www-bdnew.fnal.gov/operations/rookie_books/Concepts_v3.6.pdf)
  - Particularly chapters II-IV
- Edmund Wilson, “Particle Accelerators”
  - Concise reference on a number of major topics
  - Available in paperback (important if you are paying)
  - Good reference for a non-accelerator physicist
- Edwards and Syphers “An Introduction to the Physics of High Energy Accelerators”
  - My personal favorite
  - Concise. Scope and level just right to get a solid grasp of the topic
  - Crazy expensive, for some reason.
- Helmut Wiedemann, “Particle Accelerator Physics”
  - Probably the most complete and thorough book around (originally two volumes)
  - Well written
  - Scope and mathematical level very high
- USPAS Course: <http://uspas.fnal.gov/>

# BACKUP SLIDES

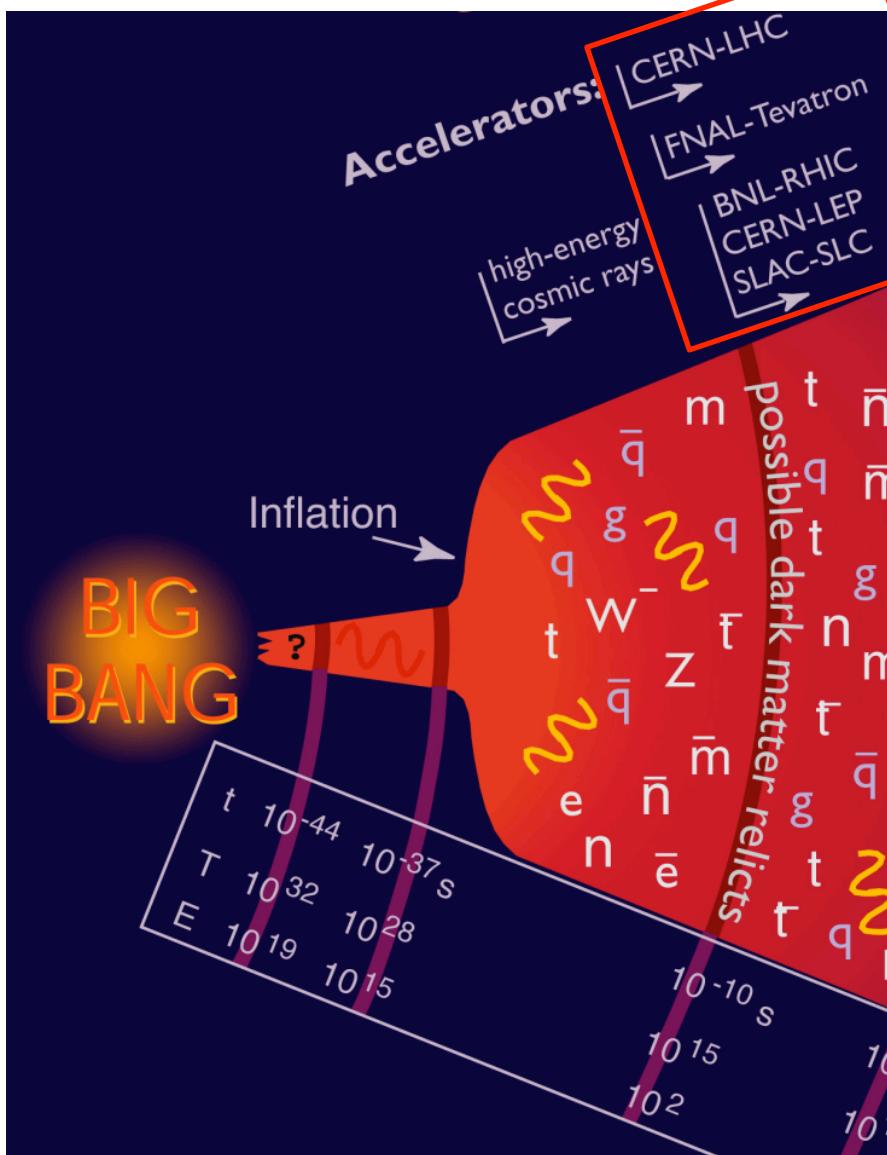

# Motivation

Going to higher energies = going back in time

# Where We Are...

- Accelerators allow us to go back 13.8 *billion years* and recreate conditions that existed a *few trillionths of a second* after the Big Bang
  - the place where our current understanding of physics breaks down.
- In addition to high energy, we need high “luminosity” that is, lots of particles interacting, to see rare processes.

# Limits to Luminosity\*

Total beam current, limited by machine protection(!), e<sup>-</sup> cloud and other instabilities

$$L = \left( \frac{\gamma f_{rev}}{4\pi} \right) \frac{n_b N_b}{\beta^*} \left[ \left( \frac{N_b}{\epsilon_N} \right) R_\phi \right]$$

$\beta^*$ , limited by

- magnet technology
- chromatic effects

“Brightness”, limited by

- Space charge blowup at low energy
- Max beam-beam tune-shift

Geometric factor, related to crossing angle...

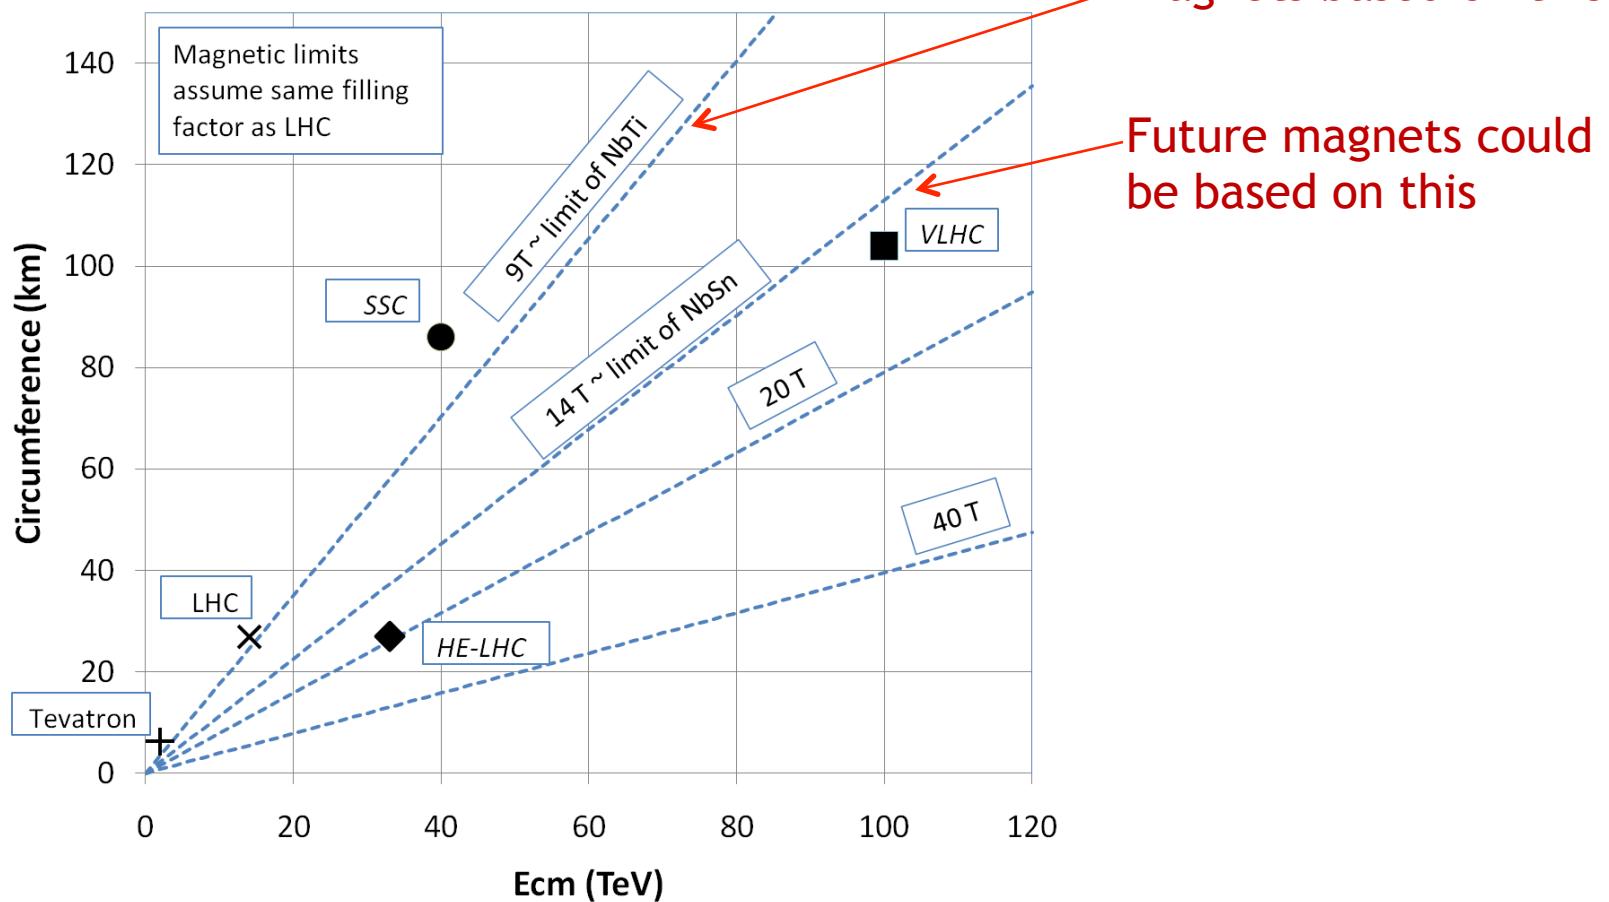

\*see, eg, F. Zimmermann, “CERN Upgrade Plans”, EPS-HEP 09, Krakow, for a thorough discussion of luminosity factors.

# What next?

- The energy of Hadron colliders is limited by feasible size and magnet technology. Options:

- Get very large (~100 km circumference)
- More powerful magnets (requires new technology)

# Future Circular Collider (FCC)

- Currently being discussed for ~2030s
- 80-100 km in circumference
- Niobium-3-Tin ( $\text{Nb}_3\text{Sn}$ ) magnets.
- ~100 TeV center of mass energy

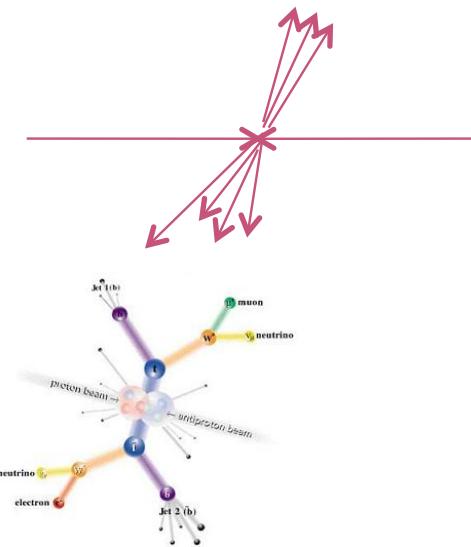

# Other Paths to the Energy Frontier

## ○ Leptons vs. Hadrons revisited

- Because 100% of the beam energy is available to the reaction, a lepton collider is competitive with a hadron collider of ~5-10 times the beam energy (depending on the physics).
- A lepton collider of >1 TeV/beam could compete with the discovery potential of the LHC
  - A lower energy lepton collider could be very useful for precision tests, but I'm talking about direct *energy frontier* discoveries.
- Unfortunately, building such a collider is VERY, VERY hard
  - Eventually, circular  $e^+e^-$  colliders will radiate away all of their energy each turn
    - LEP reached 100 GeV/beam with a 27 km circumference synchrotron!

→ Next  $e^+e^-$  collider will be linear

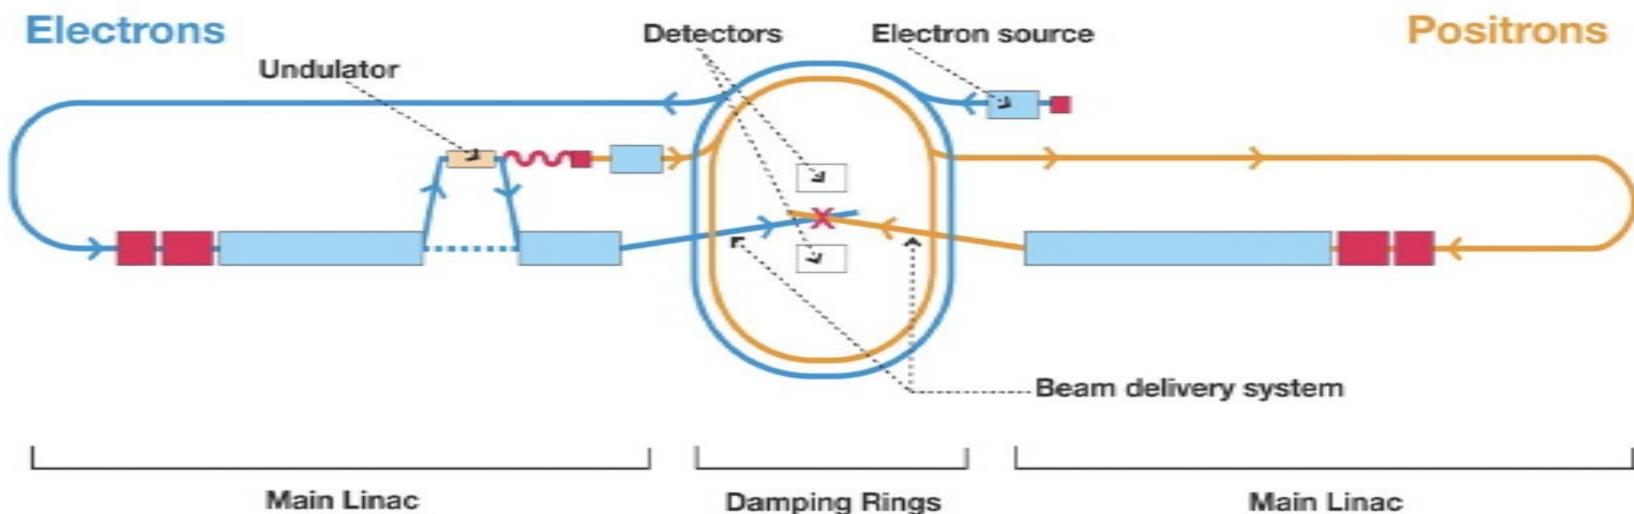

# International Linear Collider (ILC)

- LEP was the limit of circular  $e^+e^-$  colliders

- Next step must be linear collider
- Proposed ILC 30 km long,  $250 \times 250$  GeV  $e^+e^-$  (NOT energy frontier)

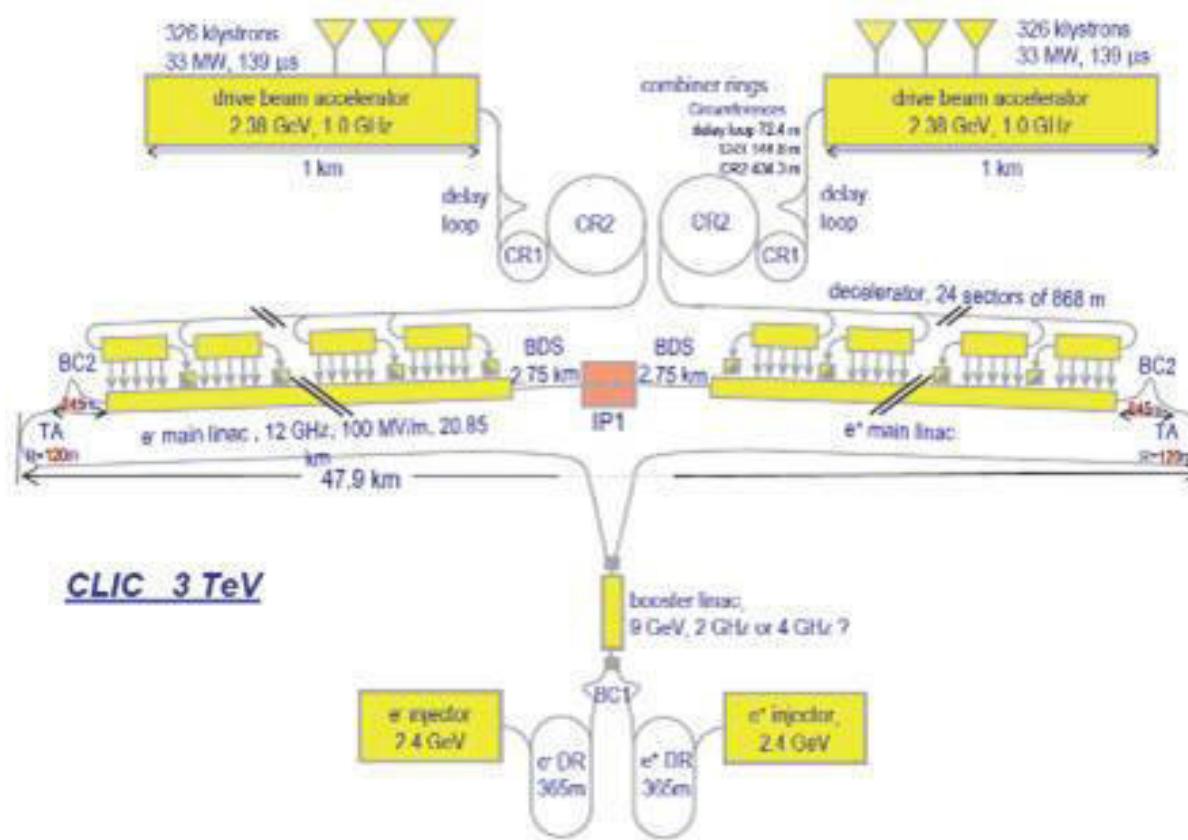

- We don't yet know whether that's high enough energy to be interesting
  - Need to wait for LHC results
  - What if we need more?

# “Compact” (ha ha) Linear Collider (CLIC)?

- Use low energy, high current electron beams to drive high energy accelerating structures

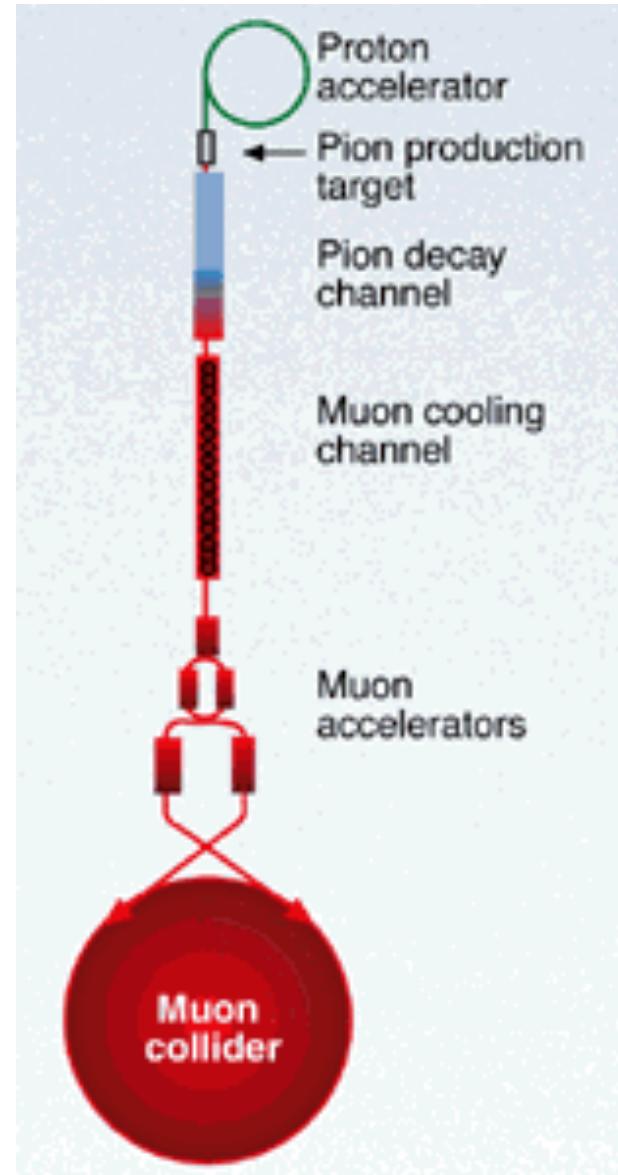

- Up to 1.5 x 1.5 TeV, but VERY, VERY hard

# Muon colliders?

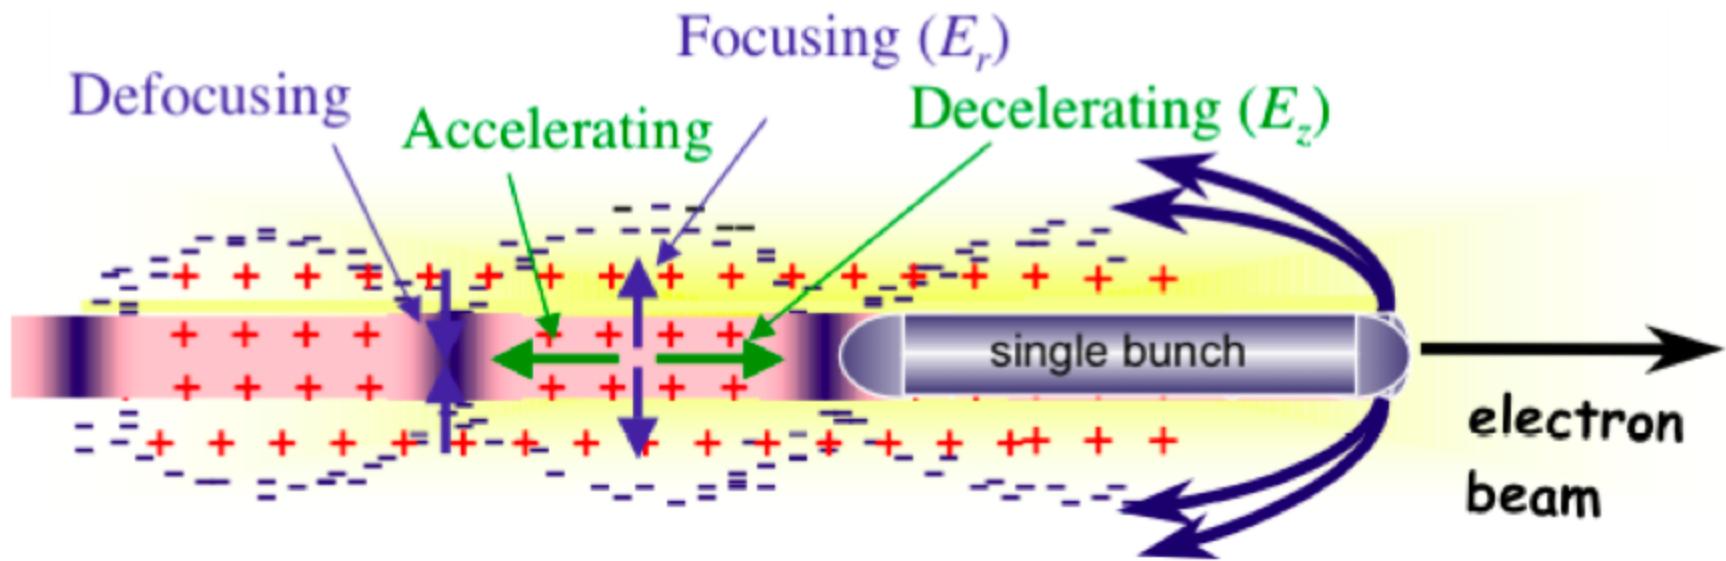

- Muons are pointlike, like electrons, but because they're heavier, synchrotron radiation is much less of a problem.
- Unfortunately, muons are unstable, so you have to produce them, cool them, and collide them, before they decay.

# Wakefield accelerators?

- Many advances have been made in exploiting the huge fields that are produced in plasma oscillations.

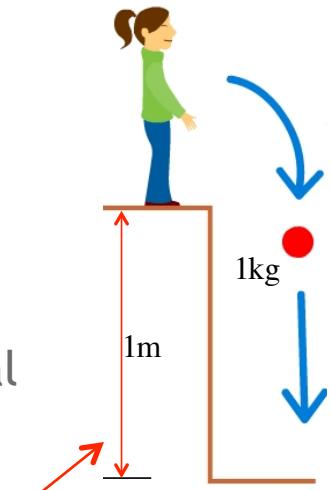

- Potential for accelerating gradients many orders of magnitude beyond RF cavities.
- Still a long way to go for a practical accelerator.

# Units of energy: Electron Volts

- An “electron-volt” is the energy gained by a particle of unit charge is accelerated over 1V potential
- It is *really small*
  - $1\text{eV} = 1.6 \times 10^{-19}$  ( $= .0000000000000000000016$ ) Joules - our usual unit of energy.
  - A 1 kg weight dropped 1m would have  $6 \times 10^{18}$  eV of energy!
- On the other hand, it’s a very useful unit when talking about individual particles
  - If we accelerate a proton using an electrical potential, we know exactly what the energy is.
  - It’s also useful when thinking about mass/energy equivalence

$$(\text{proton mass}) \times c^2 = 938,000,000 \text{ eV} \approx 1 \text{ billion eV} = 1 \text{ GeV}$$

$$(\text{electron mass}) \times c^2 = 511,000 \text{ eV} \approx \frac{1}{2} \text{ MeV}$$

# Another way to look at energy...

- Quantum mechanics tells us all particles have a wavelength

## “Planck Constant”

$$\lambda = \frac{h}{p} \approx \frac{\text{(size of a proton)}}{\text{Energy (in GeV)}}$$

momentum

as  $v$  approaches  $c$

- So going to higher energy allows us to probe smaller and smaller scales

- If we put the high equivalent mass and the small scales together, we have...

# Understanding Energy

- High Energy Physics is based on Einstein's equivalence of Mass and Energy

$$E = mc^2$$

- All reactions involve some mass changing either to or from energy

Chemical Explosion

.00000005% of mass converted to energy.

Hydrogen Bomb

~.1% (of just the Hydrogen!) converted.

- If we could convert a kilogram of mass entirely to energy, it would supply all the electricity in the United States for *almost a day*.

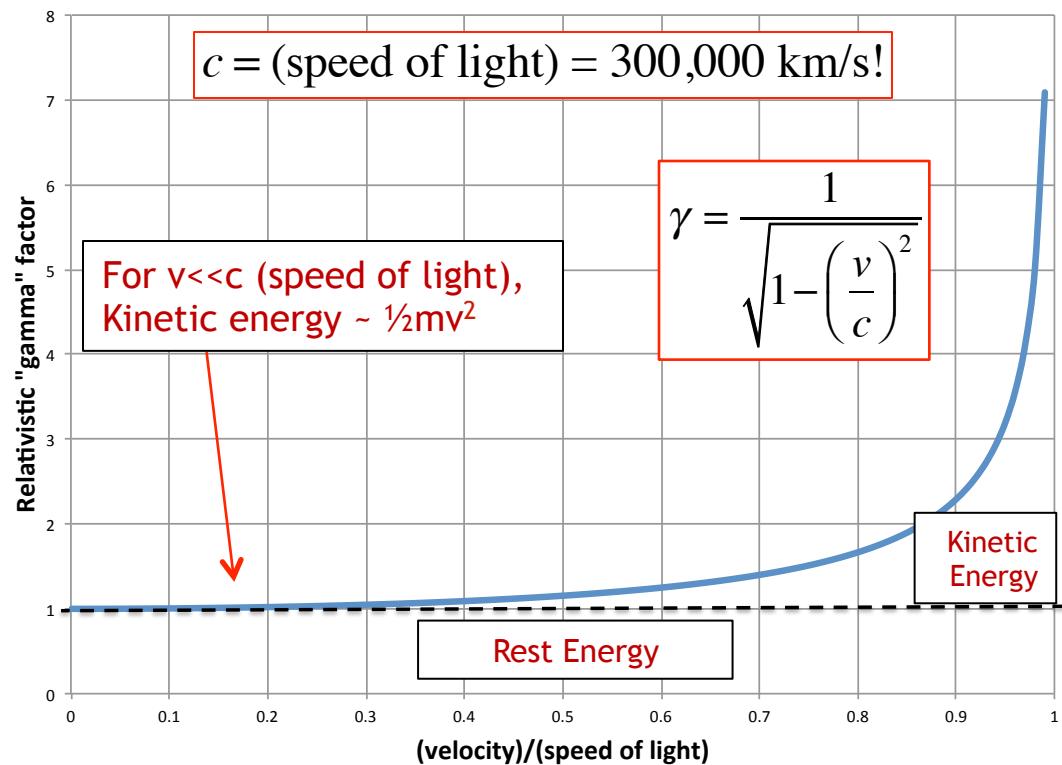

# Kinetic Energy

- A body in motion will have a total energy given by

$$E = \frac{mc^2}{\sqrt{1 - \left(\frac{v}{c}\right)^2}} \equiv \gamma mc^2$$

- The difference between this and  $mc^2$  is called the “kinetic energy”
- Here are some examples of kinetic energy

# Equations of Motion

- If we go through the equations, keeping only terms which are linear in  $x$  and  $y$ , we get

Local curvature due to dipole field (function of  $s$ )

$$\frac{\partial^2 x}{\partial s^2} + \left( \frac{1}{\rho(s)^2} + \frac{1}{(B\rho)} \frac{\partial B_y}{\partial x} \right) x = 0$$

$$\frac{\partial^2 y}{\partial s^2} - \frac{1}{(B\rho)} \frac{\partial B_x}{\partial y} y = 0$$

Periodic

$$x'' + K_x(s)x = 0$$

$$y'' + K_y(s)y = 0$$

Independent of energy for synchrotron!

“Rigidity”

- Most generic treatment of small deviation from equilibrium in periodic system
  - “Hill’s Equation”, first used to study the stability of the lunar orbit
- Looks “kinda sorta” like a harmonic oscillator. If  $K$  is constant, then

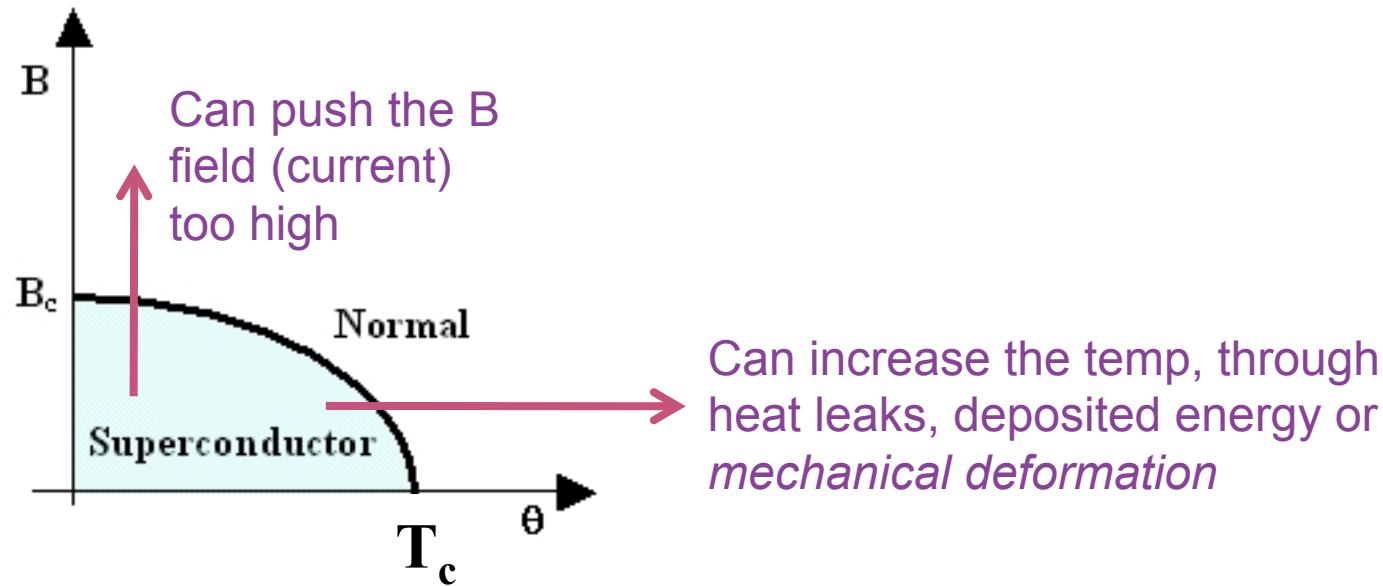

$$x(s) = A \sin(\sqrt{K}x + \delta) \quad \text{so try} \quad x(s) = Aw(s) \sin(\psi(s) + \delta)$$

not surprisingly, this works!

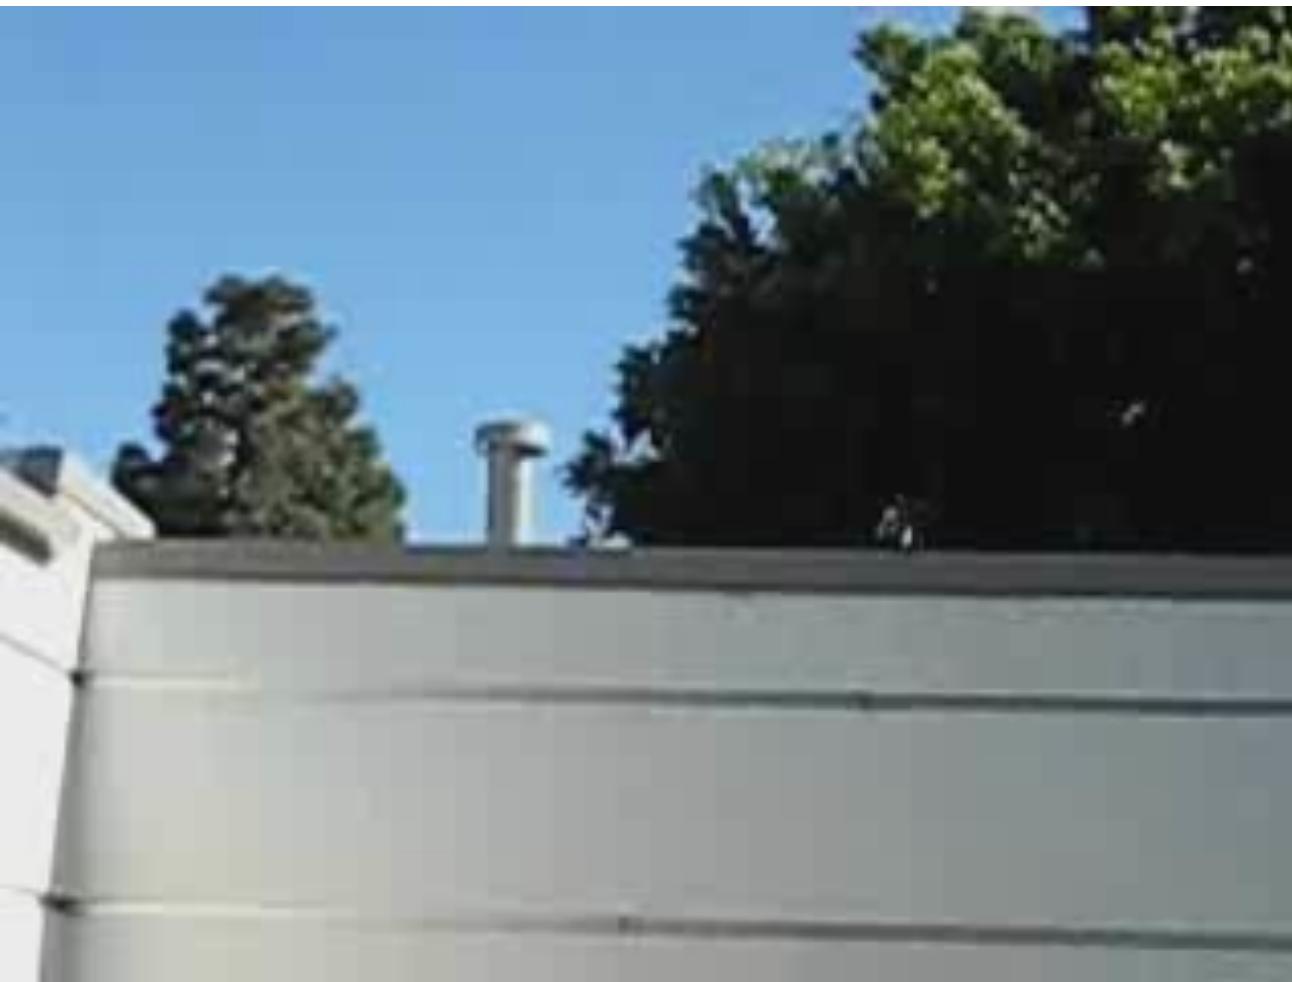

# When is a superconductor not a superconductor?

- Superconductor can change phase back to normal conductor by crossing the “critical surface”

- When this happens, the conductor heats quickly, causing the surrounding conductor to go normal and dumping lots of heat into the liquid Helium → “quench”
  - all of the energy stored in the magnet must be dissipated in some way
- Dealing with quenches is the single biggest issue for any superconducting synchrotron!

# Quench Example: MRI Magnet\*

\*pulled off the web. We recover our Helium.

# Partial LHC Timeline

- 1994:
  - The CERN Council formally approves the LHC
- 2000:
  - LEP completes its final run
  - First dipole magnet delivered
- 2007
  - Last magnet delivered
  - First sector cold
  - All interconnections completed
- 2008
  - Accelerator complete
  - Last public access
  - Ring cold and under vacuum
  - September 10<sup>th</sup>: First circulating beam
  - September 19<sup>th</sup>: BAD accident brings beam down for almost 2 years

# It begins...

- 9:35 - First beam injected
- 9:58 - beam past CMS to point 6 dump
- 10:15 - beam to point 1 (ATLAS)
- 10:26 - First turn!
- ...and there was much rejoicing

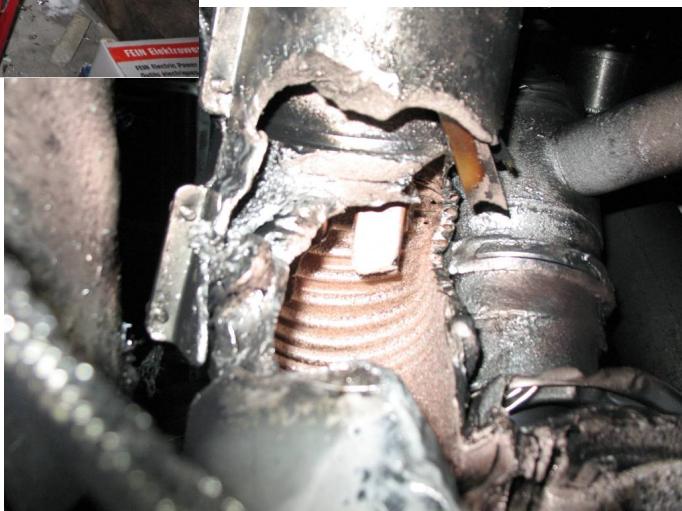

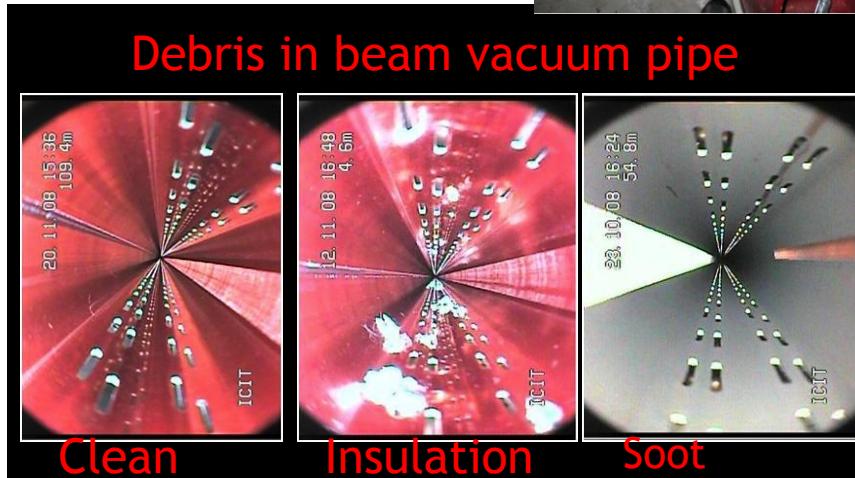

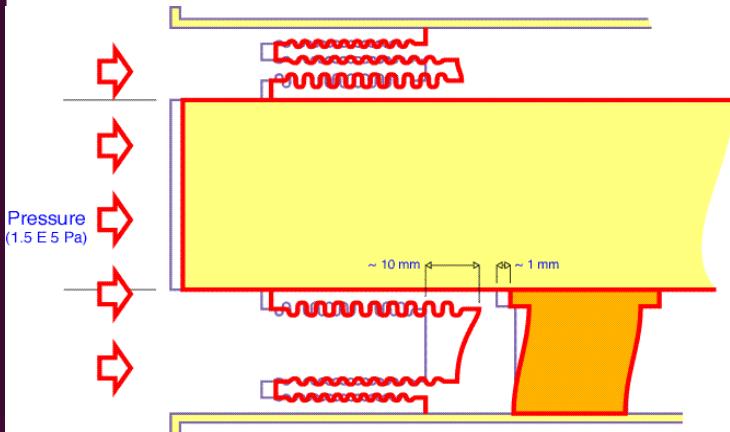

Commissioning proceeded smoothly and rapidly until September 19<sup>th</sup>, when *something* very bad happened

# It Ends: “The Incident”

- A quench developed into an arc
- This caused Helium to boil
- The resulting pressure did a great deal of damage, and kept the machine off for more than

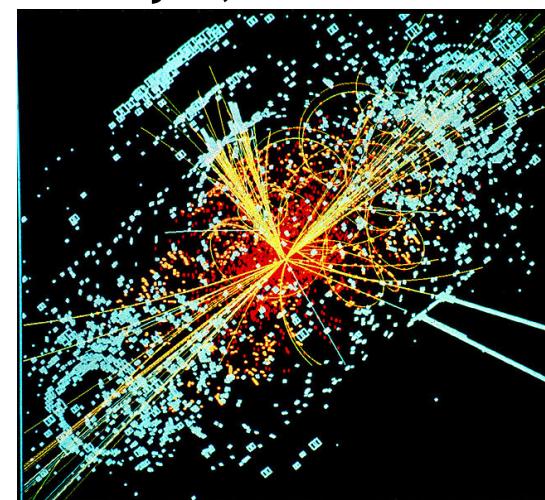

Secondary arcs

Summer Lecture Series, June 9, 2015

# After the Incident

- The LHC was off for almost two years to repair the damage and partially address the cause.
- 2010: Came up at a reduced energy: 3.5 TeV + 3.5 TeV
- 2012: Increased energy to 4 TeV + 4 TeV
- Announced the discovery of Higgs particle July 4, 2012
  - Responsible to giving particles mass
  - Last piece of the “Standard Model”

- 2013 Nobel prize to Higgs and Englert

## Plans for LHC

- The LHC will be the centerpiece of the world's energy frontier physics program for at least the next 15-20 years.
- The machine is currently of to fix the issue which cause “the incident”
- Accelerator will come back up in 2015 at something close to the design energy
  - At least 6.5 TeV/beam
- Planning major upgrades to increase luminosity in ~2023

# Some other important accelerators (past):

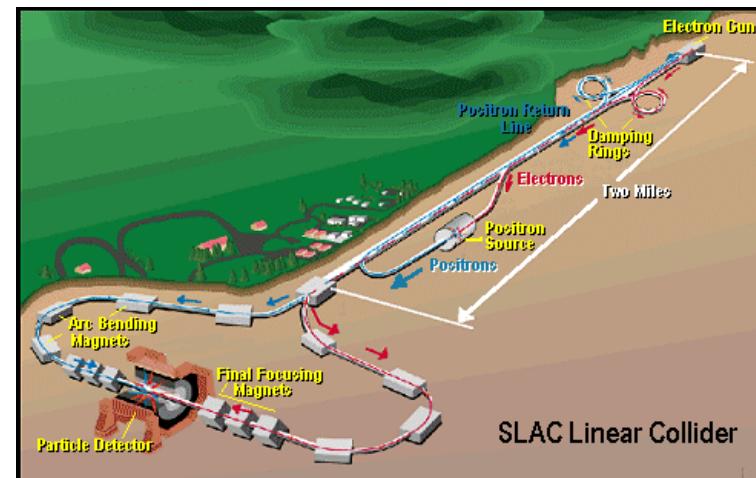

## LEP (at CERN):

- 27 km in circumference
- $e^+e^-$
- Primarily at  $2E=M_Z$  (90 GeV)
- Pushed to  $E_{CM}=200\text{GeV}$
- $L = 2E31$
- **Highest energy *circular*  $e^+e^-$  collider that will ever be built.**
- Tunnel now houses LHC

## SLC (at SLAC):

- 2 km long LINAC accelerated electrons AND positrons on opposite phases.
- $2E=M_Z$  (90 GeV)
- polarized
- $L = 3E30$
- **Proof of principle for linear collider**

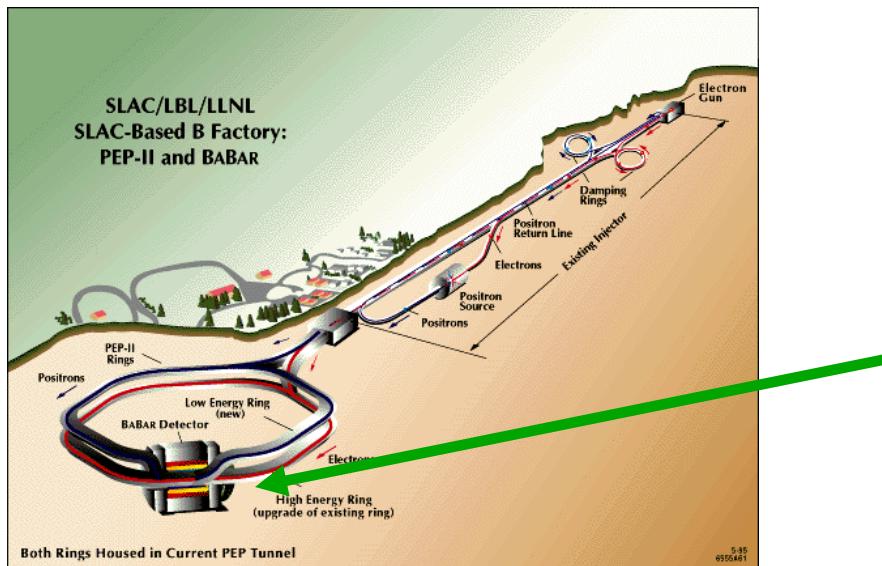

# B-Factories

- B-Factories collide  $e^+e^-$  at  $E_{CM} = M(\Upsilon(4S))$ .
- Asymmetric beam energy (moving center of mass) allows for time-dependent measurement of B-decays to study CP violation.

## KEKB (Belle Experiment):

- Located at KEK (Japan)
- $8\text{GeV } e^- \times 3.5\text{ GeV } e^+$
- Peak luminosity  $>1\text{e}34$

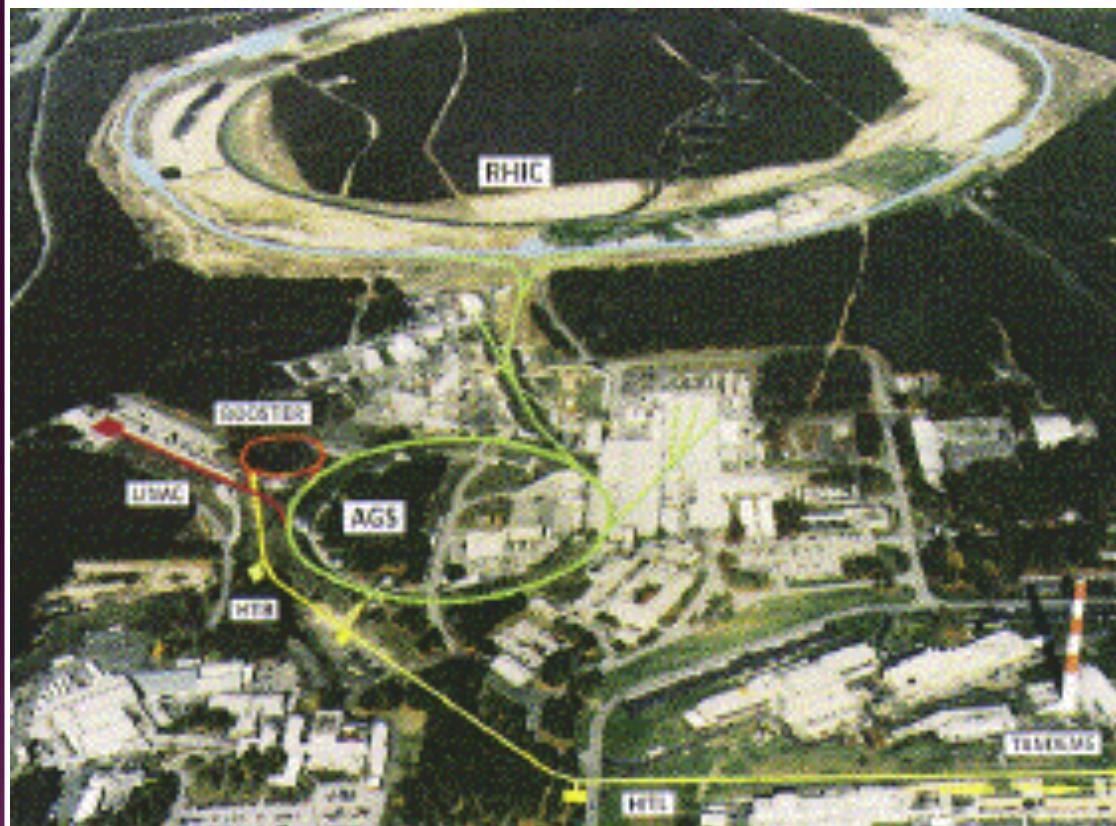

## PEP-II (BaBar Experiment)

- Located at SLAC (USA)
- $9\text{GeV } e^- \times 3.1\text{ GeV } e^+$
- Peak luminosity  $>1\text{e}34$

# Relativistic Heavy Ion Collider (RHIC)

- Located at Brookhaven:
- Can collide protons (at 28.1 GeV) and many types of ions up to Gold (at 11 GeV/amu).
- Luminosity:  $2E26$  for Gold
- **Goal: heavy ion physics, quark-gluon plasma, ??**

# Continuous Electron Beam Accelerator Facility (CEBAF)

Jlab, the aerial view

- Locate at Jefferson Laboratory, Newport News, VA
- 6GeV e- at 200 uA continuous current
- Nuclear physics, precision spectroscopy, etc
