Dipole Error (or Correction)

• Recall our generic transfer matrix

$$\begin{pmatrix} x_1 \\ x_1' \end{pmatrix} = \begin{pmatrix} \sqrt{\frac{\beta_1}{\beta_0}} (\cos \Delta \psi + \alpha_0 \sin \Delta \psi) & \sqrt{\beta_0 \beta_1} \sin \Delta \psi \\ \frac{1}{\sqrt{\beta_0 \beta_1}} ((\alpha_0 - \alpha_1) \cos \Delta \psi - (1 + \alpha_0 \alpha_1) \sin \Delta \psi) & \sqrt{\frac{\beta_0}{\beta_1}} (\cos \Delta \psi - \alpha_1 \sin \Delta \psi) \end{pmatrix} \begin{pmatrix} x_0 \\ x_0' \end{pmatrix}$$

 \odot If we use a dipole to introduce a small bend Θ at one point, it will in general propagate as

$$\begin{pmatrix} x(\Delta\psi) \\ x'(\Delta\psi) \end{pmatrix} = \begin{pmatrix} \sqrt{\frac{\beta(s)}{\beta_0}} \left(\cos \Delta\psi + \alpha_0 \sin \Delta\psi\right) & \sqrt{\beta_0\beta(s)} \sin \Delta\psi \\ \frac{1}{\sqrt{\beta_0\beta(s)}} \left(\left(\alpha_0 - \alpha(s)\right) \cos \Delta\psi - \left(1 + \alpha_0\alpha(s)\right) \sin \Delta\psi\right) & \sqrt{\frac{\beta_0}{\beta(s)}} \left(\cos \Delta\psi - \alpha(s) \sin \Delta\psi\right) \end{pmatrix} \begin{pmatrix} 0 \\ \theta \end{pmatrix}$$

$$x(\Delta \psi) = \theta \sqrt{\beta_0 \beta(s) \sin \Delta \psi}$$

$$x'(\Delta \psi) = \theta \sqrt{\frac{\beta_0}{\beta(s)}} \left(\cos \Delta \psi - \alpha(s) \sin \Delta \psi\right)$$

Closed Orbit Distortion ("cusp")

- We place a dipole at one point in a ring which bends the beam by an amount Θ.
- The new equilibrium orbit will be defined by a trajectory which goes once around the ring, through the dipole, and then returns to its exact initial conditions. That is

$$\mathbf{M} \begin{pmatrix} x_0 \\ x'_0 \end{pmatrix} + \begin{pmatrix} 0 \\ \theta \end{pmatrix} = \begin{pmatrix} x_0 \\ x'_0 \end{pmatrix} \Rightarrow (\mathbf{I} - \mathbf{M}) \begin{pmatrix} x_0 \\ x'_0 \end{pmatrix} = \begin{pmatrix} 0 \\ \theta \end{pmatrix}$$
$$\Rightarrow \begin{pmatrix} x_0 \\ x'_0 \end{pmatrix} = (\mathbf{I} - \mathbf{M})^{-1} \begin{pmatrix} 0 \\ \theta \end{pmatrix}$$

Quadrupole Errors

We can express the matrix for a complete revolution at a point as

$$\mathbf{M}(s) = \begin{pmatrix} \cos 2\pi v + \alpha(s)\sin 2\pi v & \beta(s)\sin 2\pi v \\ -\gamma(s)\sin 2\pi v & \cos 2\pi v - \alpha(s)\sin 2\pi v \end{pmatrix}$$

• If we add focusing quad at this point, we have

$$\mathbf{M}'(s) = \begin{pmatrix} \cos 2\pi v_0 + \alpha(s)\sin 2\pi v_0 & \beta(s)\sin 2\pi v_0 \\ -\gamma(s)\sin 2\pi v_0 & \cos 2\pi v - \alpha(s)\sin 2\pi v_0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -\frac{1}{f} & 1 \end{pmatrix}$$

$$= \begin{pmatrix} \cos 2\pi v_0 + \alpha(s)\sin 2\pi v_0 - \frac{\beta(s)}{f}\sin 2\pi v_0 & \beta(s)\sin 2\pi v_0 \\ -\gamma(s)\sin 2\pi v_0 - \frac{1}{f}(\cos 2\pi v_0 - \alpha(s)\sin 2\pi v_0) & \cos 2\pi v_0 - \alpha(s)\sin 2\pi v_0 \end{pmatrix}$$

We calculate the trace to find the new tune

• We calculate the trace to find the new tune
$$\cos 2\pi v = \frac{1}{2} \mathbf{M}'(s) = \cos 2\pi v_0 - \frac{1}{2f} \beta(s) \sin 2\pi v_0$$
• For small errors

$$\cos 2\pi (v_0 + \Delta v) \approx \cos 2\pi v_0 - 2\pi \sin 2\pi v_0 \Delta v = \cos 2\pi v_0 - \frac{1}{2f} \beta(s) \sin 2\pi v_0$$

$$\Rightarrow \Delta v = \frac{1}{4\pi} \frac{\beta(s)}{f}$$

Total Tune Shift

• The focal length associated with a local anomalous gradient is

$$d\left(\frac{1}{f}\right) = \frac{B'}{\left(B\rho\right)}ds$$

So the total tune shift is

$$\Delta v = \frac{1}{4\pi} \oint \beta(s) \frac{B'(s)}{(B\rho)} ds$$
